SOCIAL FORCES

AN INTERNATIONAL JOURNAL OF SOCIAL RESEARCH
ASSOCIATED WITH THE SOUTHERN SOCIOLOGICAL SOCIETY

VOLUME 74: NUMBER 1 SEPTEMBER 1995

IN GENERAL

1. Mail manuscripts (5 copies) to: Social Forces, Department of Sociology, Hamilton Hall, University of North Carolina, Chapel Hill, NC 27599-3210.
2. The paper must not be submitted to another journal while under review by SF.
3. Enclose a $15 processing fee. Papers are not reviewed until this fee is paid. The fee is waived for papers solely by currently enrolled students.
4. Manuscripts are not returned to authors.
5. Authors transfer copyright to SF. Permission fees for reprint of articles are split between authors and journal.

PREPARATION OF MANUSCRIPTS

1. For review, papers may be submitted in the form used by SF, American Sociological Association or other major sociological journals. Authors of accepted manuscripts are responsible for putting them into SF form.
2. **Format, Organization, and Style** Submit 5 clearly legible copies on 8 ½ by 11 good quality white paper. Double space typing throughout. For an accepted paper being revised to fit SF style, leave at least 1" margins; do not justify margins if using a word processor.

i. **Order** Organize the manuscript in this order: cover page; abstract; text; endnotes; references; tables; figures.

ii. **Cover Page** Give title; author(s); affiliation(s); and a footnote (*) indicating name and address of the author to whom requests for offprints or other correspondence should be sent ("Direct correspondence to ___") and acknowledgment (if any) of financial or other assistance.

iii. **Abstract** On a separate page, preceding the text, write a summary, 125 or fewer words (70 or fewer for a Research Note).

iv. **Endnotes** Use only for substantive comments, bearing on content. Number consecutively from 1, double space, and append on a separate page.

v. **Tables** Type each table on a separate page. Insert a location note — "Table 1 about here" — in the text. For substantive footnotes relating to a table or figure use lowercase letters. Use tabs to separate columns.

vi. **Figures** Must be artist-drawn, camera ready. Do not send original copy with a manuscript submitted for review. For review, figures may be roughly drawn but they must be neat and legible. For footnotes to figures, use same symbols as for footnotes to tables.

vii. **Mathematical Symbols** (and others likely to be obscure to compositor) Clarify with encircled words written in the margin.

viii. **References in Text** Indicate sources as illustrated below:

1. when author's name is in text — Lipset (1960); when author's name is not in text (Lipset 1960)
2. use page numbers only for direct quotations or specific notes or table — (Braudel 1969:213-14)
3. for more than 3 authors use "et al."
4. with more than 1 reference to an author in the same year, distinguish them by the use of letters (a,b,c) with year of publication (1975a)
5. earlier publication should precede later publication in brackets with parentheses (Tocqueville [1835] 1956)
6. enclose a series of references — in alphabetical order — in parentheses, separated by semicolons (e.g., Adler 1975; Adler & Simon 1979; Anderson, Chiricos & Waldo 1977; Bernstein et al. 1977; Chesney-Ling 1973a, 1973b).

ix. **References Following Endnotes** List authors alphabetically, by surname. Spell out first names of all authors and editors. For authors with more than one work cited, list works earliest to latest. For articles, next give title of article (caps and lower case), name of journal, volume number, and pagination. For books and monographs, give title, followed by publisher.

x. **Format of References**
Please spell out the first names of all authors and editors, unless they use only their initials or a first initial and a middle name in the source cited (e.g., Paul Radin, T.S. Eliot, and J. Owen Dorsey).

Elder, Glen H. 1975. "Age Differentiation and the Life Course." Pp. 165-90 in *Annual Review of Sociology*. Vol. 1, edited by Alex Inkeles, James Coleman, and Neil Smelser. Annual Reviews.

BOOK REVIEWS

The Practical Consequences of Sociology's Pursuit of "Justice for All"*

THOMAS C. HOOD, *University of Tennessee, Knoxville*

Abstract

The following essay explores the consequences of American sociology's commitment to the value, "justice for all." Concentrating on the idea of substantive justice, the article assesses consequences for the generation of sociological knowledge, the teaching of sociology, and sociology's place in the development of public policy. Several conclusions are drawn about the nature of justice and the practice of sociology. Sociological knowledge is viewed as particularistic. The teaching of sociology competes with other disciplines in curriculum politics in American higher education. Sociology, properly taught, has much to offer; its contribution to public policy suggests a strong respect for other value systems and a recognition of global interdependence.

Thirty-three years ago, Pitirim A. Sorokin's (1962) article, "The Practical Influence of 'Impractical' Generalizing Sociological Theories," was published. His impressive, and perhaps self-serving, documentation of the impact of the theories of Marx and Gandhi, Aristotle and St. Augustine, Hegel, Marx, Spencer, and Freud serve to support his conclusion that the role of builder of grand systems of social thought is a most important mission. Kurt Lewin has been quoted as saying that there is nothing as practical as a good theory (Marrow 1969). This article will not develop a new or groundbreaking definition of *justice.* The arguments offered will not solidify sociology's claim to the position of queen of the sciences. The following essay will develop the following thesis. *American sociology has a basic value commitment and advocacy stance embedded in its theory and practice. This value is that justice practiced correctly is blind — all are equal before the law. All persons are entitled to a chance to succeed. This commitment leads to a critical stance toward social institutions that are seen as organizations and*

** This article is a slight revision of the presidential address given 7 April, 1995 at the Southern Sociological Society, Atlanta. The author wishes to thank Diana Harris, Donald Clelland and Michael Benson for criticism and suggestions and to express particular gratitude to Bennett Judkins and John Gaventa for the inspiration provided by their scholarly work and their work in organizing the 1995 program for the Southern Sociological Society Annual Meeting.* *Direct correspondence to the author at Department of Sociology, 901 McClung Tower, University of Tennessee, Knoxville, TN 37996-0490.  Social Forces, September 1995, 74(1):1-14

customs that tend to perpetuate inequalities of economic position, prestige and political power rather than working to eliminate them. After stating three points regarding the definition of justice, the essay develops the consequences of this value position for sociological knowledge, for sociology as a teaching enterprise in the American college and university, and for sociology as it has implications for social policy.

Defining Justice

Definitions of *justice* abound. An excellent review article from a social psychological point of view appears in the new volume, *Sociological Perspectives on Social Psychology*, edited by Karen S. Cook, Gary Alan Fine, and James S. House (Hegtvedt & Markovsky 1995). Their article concentrates on research on distributive justice and procedural justice.[1] This article concentrates on what the authors of *Habits of the Heart* call substantive justice or "a matter of the institutional order of society as a whole and its justice or fairness" (Bellah et al. 1985:334).

Justice requires agreement about the purposes or ends of life and not simply procedures for resolving disputes or the fairness of the society's system of rewards or of its distribution of goods and opportunities.

I agree with the authors of *Habits of the Heart* (Bellah et al. 1985) and *The Good Society* (Bellah et al. 1991) when they say that the conception of justice in American society is founded in the the Judaeo-Christian tradition. Whether talking about the first governor of Massachusetts, John Winthrop, Thomas Jefferson, or a contemporary Jewish child, the subjectivity of American justice is legitimated by belief in some higher authority. Consider the Exodus story.

> [It] binds together all sorts of Americans from the beginnings of our history to the present. In 1988 the thirteen-year-old daughter of a Jewish immigrant from South Africa offered this text as the reading for her bat mitzvah: "When you reap your harvest in the field, and forget a sheaf in the field . . . it is to go to the resident alien, the orphan and the widow, that the Lord your God may bless you in all your enterprises. . . . You must remember that you were once a slave yourself in the land of Egypt; that is why I am commanding you to do this" (Deuteronomy 24:19). She is retelling a fragment of a story that Americans from John Winthrop to Martin Luther King have told over and over again to make the same point. It is a story that helps to define the consciousness of our society. A good society for Americans is one in which our children may still retell such a story with hope that they can at least partially live up to its meaning. As long as we define our national identity in terms of being able to create and sustain such a society, we will have a self-understanding that can be defended and pursued in the great society of our interdependent world. (Bellah et al. 1991:247)

Two points to remember about justice as used in this essay are that the concern is substantive justice and that in American sociology the foundation for understanding substantive justice comes from the Judaeo-Christian tradition. The third point is that American sociology often selects problems to investigate that examine the American ideal of "justice for all." This is a crucial point in that the *all* in sociology includes all subcultures and all societies. The cultural

relativism advocated by Ruth Benedict ([1934] 1959) in the 1930s has become the accepted value position of the discipline:

> We must be willing to take account of changing normalities even when the question is of the morality in which we were bred. Just as we are handicapped in dealing with ethical problems so long as we hold to an absolute definition of morality, so we are handicapped in dealing with human society so long as we identify our local normalities with the inevitable necessities of existence. (234)

Sociologists have responded to her call for this commitment and cultural relativity (now called "multiculturalism") is taught not only in sociology courses but across the curriculum. With Benedict a number of people would say that we are well on the way to accomplishing the task of formulating "a more realistic social faith accepting as grounds of hope and as new bases for tolerance the coexisting and equally valid patterns of life which mankind has created for itself from the raw materials of existence" (240).

I suspect that attentive readers are thinking, "Didn't he just claim that American conceptions of justice are founded in the Judaeo-Christian ethic, which is a particular world view and value system!" "Aren't sociologists committed to the view that *all* value systems are legimate, have their own logic, and deserve respect. Isn't there some potential for conflict here?" The answer is Yes. There is potential for conflict, but these are the three definitional starting points for the essay.

1. Substantive justice is a value embedded in the fairness of the institutional order of the society.

2. The American conception of fairness or what is just is derived from or legitimated by a belief in a higher conception of justice or righteousness found in the Judaeo-Christian tradition.

3. Justice for all as taught by sociologists means that justice should respect the value system of the particular subculture or society within which the action is seen as just or unjust. (Thou shalt not violate the "prime directive" of imposing one's value judgments on a subculture or society different from one's own.)

Justice and the Creation of Sociological Knowledge

Given this conception of justice what is the current impact on the practice of sociological research? Over the last 15 years or so, American sociology has emerged from a period during which logical positivism and sample surveys using quantitative operational definitions were the dominant form of data collection. Now qualitative methodologies and alternative epistemologies are being advocated as a way to achieve a fuller understanding of human social behavior. The early works, Monica B. Morris, *An Excursion into Creative Sociology* (1977) and Jack D. Douglas, *Introduction to the Sociologies of Everyday Life* (1980), surveyed the emerging movements of ethnomethodology, phenomenology, existential sociology, trends in symbolic interactionism and the work of Erving Goffman. Increasingly people came to realize the importance of language not just in the sense of precise operational definitions but in the contribution of language and nonverbal communication to the expectations and understandings

that constitute microfoundations of social order. In some ways this was a natural response to the philosophical treatise published by Berger and Luckmann in the mid-1960s, *The Social Construction of Reality* (1966).

In addition to this trend, by the mid-1970s, people were criticizing otherwise fine pieces of research for the implicit value judgments in the descriptive statements about the populations they were studying. For example, some reviews of Kai Erikson's, *Everything in its Path,* (a Sorokin Award winning book) criticized the description of the inhabitants of Buffalo Creek and other mountain communities as biased (Billings & Maggard 1978; Dynes 1978). Other works, such as Rodger Cunningham's *Apples on the Flood* (1987), critique the work of Weller and other scholars on Appalachia by questioning their failure to understand the point of view (subjective meanings) of those they were studying.

The newer methods listed above ask the question that Benedict said we must ask about any society or subculture — namely, what is the system of values in that society or subculture. Cunningham shows the failure of many scholars to capture the essence of Appalachians. He suggests that these scholars, like Arnold Toynbee, Michael Harrington, or Jack Weller, may approach the Appalachian with the ideal of objective observation, but use a standard of the outside culture as a reference point and view the Appalachian as a child not capable of acting responsibly in its own best self-interest. The dominant culture "America" must tell "hillbillies" how to act responsibly. Recent shows like "The Beverly Hillbillies" do not offend our sensibilities in the way that "Amos and Andy" did, because we regard the caricatures offered as nothing more than exaggerated portrayals of real differences.

Cunningham (1987) argues that:

> the dominator implicitly denies the dominated an inner self and an ability to think and act on one's own behalf (Laing 1971:101). Such disconfirmation can take "benevolent," patronizing forms, which are perhaps the most damaging — for example, the attitude expressed in Jack Weller's (1966) injunction, "Let us begin to guide the mountain man toward wholeness" (150). The attitude behind such a statement was laid bare by Rupert Vance when he wrote that Weller, "because he came as a missionary . . . brought the objectivity of the stranger. Finally he came to know these people better than they know themselves" (v). Here the positivist ideal of "objectivity" is explicitly invoked as a means of gaining knowledge of the other which is superior to one's own knowledge of who he or she is. Truly, "violence cannot be seen through the sights of positivism" (Laing 1967:51). To connect this with our earlier themes, let us note that addressed to an adult, the call to "grow up" (in social terms, to attain "wholeness") is by implication just as infantilizing as the command to remain a child (Rogin 1975:210). Just so the call to "us" outsiders to "guide the mountain man toward wholeness" disconfirms the real agency of the mountaineer, refuses to recognize his or her real existence, and thus defeats its stated goal. (118)

Slim's Table, a recent study of African American males, shows the promise for community in sustaining American culture (Duneier 1992). Carefully constructed and based on participant observation, the work demonstrates the failure of past studies of this group to avoid stereotypes commonly voiced in the press and even sociological literature. Duneier points out that past ethnographies and studies of black males by American sociologists have many positive qualities. Nevertheless, the authors made "patently inaccurate inferenc-

es about blacks or unfair generalizations from selective samples that reinforce, rather than question, the most basic stereotypes. . . . In the process of developing deeper understandings, sociologists casually make demeaning assertions about the nature of black men" (142).

In one of the most perceptive treatments of this problem, Patricia Hill Collins (1990) points out that positivist methodological approaches require the distancing of the researcher from the object of study; removing emotions from the research process; limiting the role of ethics and values in the research process to the rights of human subjects; presenting results in an adversarial fashion to determine which argument "can withstand the greatest assault and survive intact" (205).

We are indebted to a number of writers for suggesting to us that alternatives to positivism, which may be quite appropriate as an epistemology for investigating universalistic relationships, exist. Collins has built on the work of Gilligan (1982) and on *Women's Ways of Knowing* (Belenky et al. 1986) to suggest one alternative epistemology to the assumptions of positivism. Patricia Hill Collins's award winning book, *Black Feminist Thought,* offers the reader an alternative epistemology for exploring the kinds of social relationships that Parsons and Shils (1962) labelled "particularistic." In her chapter, "Toward an Afrocentric Feminist Epistemology," she offers the following dimensions of an alternative epistemology. First, she presents an emphasis on concrete experience with "practical images as its symbolic vehicles." Second, she provides dialogue and connectedness as criteria for methodological adequacy. "A primary epistemological assumption underlying the use of dialogue in assessing knowledge claims is that connectedness rather than separation is an essential component of the knowledge validation process" (Belenky et al. 1986:18). Third, an ethic of caring is posited which includes the idea of unique individual expressiveness, the use of emotion in dialogue, and the ability to demonstrate empathy. Finally, the epistemology includes an ethic of personal accountability (Collins 1990:201-20).

Assessments of an individual's knowledge claims simultaneously evaluate an individual's character, values, and ethics. African Americans reject the Eurocentric, masculinist belief that probing into an individual's personal viewpoint is outside the boundaries of discussion. Rather, all views expressed and actions taken are thought to derive from a central set of core beliefs that cannot be other than personal (Collins 1990:218).

Obviously this kind of epistemology takes a very different kind of view of the statement with "justice for all" than does a positivistic approach which emphasizes rational, value-free, impersonal, and "disinterested" (Merton 1973:275-77) discussion to arrive at truth. If ways of knowing are based within a group or within the capacities generated through individual experiences, certain topics will be distorted by survey research that assumes that individual biases of question interpretation are distributed randomly through the population being surveyed.

So what does sociological knowledge look like? First of all, sociological knowledge is not value-free but conditioned by the value system in place within the various social orders that sociologists investigate. We contend that investigators are limited by the value system that they endorse and by their ability to

understand and interpret value systems different than their own. In a sentence, sociological knowledge is embedded in the investigator's value system due to the difficulty in separating observed social action into descriptive, emotional and evaluative components.

Second, all sociological knowledge is to use a word, "particularistic." One of Talcott Parsons pattern variables (1962) reflected on how normative expectations for behavior were either applied universally ("justice is blind") or particularistically ("I can make an exception for you because you are my friend, my sister, my brother, or because you are rich"). This idea that normative expectations are not universally applied in the course of everyday life has been widely supported by experimental and survey research (e.g., see Stouffer & Toby 1951). This simply means that when we look at day-to-day conduct of social life, people are constantly making allowances with regard to the normative expectations that they have depending on the prior relationships that they have had with the individual or individuals in question. The individual or individuals in question in turn enact behavior based upon their knowledge of the cultural background in which they are interacting. If that knowledge is limited, their behavior may appear strange. I recently attended a symphony concert. Attending the same concert was a group of men dressed as women. Their behavior and dress was appropriate for middle-class women attending a somewhat dressy occasion, but clearly not all of them recognized or knew the norm of waiting until the end of all the movements of a particular piece of music before breaking into applause for the performance. These men had learned appropriate dress and demeanor for the opposite gender but some had not learned appropriate behavior for showing appreciation at a symphony concert. The behavior that we enact is always based on experience conditioned by the relationships that we are trying to maintain. This behavior emerges against the background of the universalistic understandings that exist within our culture.

What are these universalistic understanding or expectations about life within our culture? Sumner ([1906] 1960) called them mores. Certainly they are not represented by the laws that our governments enact. Those social products are no more than aging photographs of the state of the moral order or consensus at a particular point in time. The universal expectations about behavior are like Plato's forms; we glimpse them only as shadows thrown up on the walls of our little caves.[2] Yet we strive to understand the universal forms from an investigation of the particular because we wish to live orderly lives. Human beings want to be able to predict the behavior of other human beings at least to the point that our daily lives can coordinate to some degree. As Kingsley Davis (1949) said many years ago, consistency or predictability in behavior is the main criterion we use for normality or sanity.

Justice and the Place of Sociology in the American College

Since sociology is not a value-neutral pursuit and since the politics of American higher education are anything but objective, sociology can easily become an area of trouble, controversy, and conflict.

Although the percentage has declined to around 70%, according to Horowitz (1993) in the last 25 years, most sociologists remain employed in academic settings. Many of those employed in academic settings have teaching appointments or have duties that include teaching, research, and administration. Because our field includes the study of formal organizations, it seems appropriate that we have engaged in critical studies of higher education. Noble's *America by Design* (1977) reveals how far the modern American university and some colleges have come from the medieval concept of the ivory tower. The indebtedness of budgets to external support by business, industry, and governmental programs raises questions about the function of the pursuit of knowledge within the university. And because sociologists are taught to raise questions about the impact of such interdependent relationships, sociology departments have been viewed as troublesome and troubling for both sociology and the university itself. *For sociology the commitment to justice for all as a basic value in sociological investigation threatens some of the long standing institutional ties of the university to lawyers, priests, physicians, and the business community.* As CBS's "60 Minutes" recently noted some institutions derive half their funding from grants and contracts for research sponsored by government or the private sector.

Bourdieu (1993) in the book, *Sociology in Question,* puts this nicely:

> The type of social science that one can do depends on the relationship one has to the social world, and therefore on the position one occupies within that world.
>
> More precisely, this relation to the world is translated into the function that the researcher consciously or unconsciously assigns to his practice and that governs his research strategies — the objects chosen, the methods used, and so on. You may make it your goal to understand the social world, in the sense of understanding for understanding's sake. Or you may seek techniques that make it possible to manipulate it in which case you place sociology in the service of the management of the established order. . . .[3]
>
> A good number of those who describe themselves as sociologists or economists are social engineers whose function is to supply recipes to the leaders of private companies and government departments. They offer a rationalization of the practical or semi-theoretical understanding that the members of the dominant class have of the social world. (13)

A second area of conflict in higher education is the competition for students. Enrollments in the contemporary university are driven more by what is required to earn a specific degree than by the attraction to a particularly brilliant lecturer or instructor. The bachelor of arts and bachelor of science degrees are awarded on the basis of the accumulation of satisfactory grades in a specified set of courses. The political debate in the university community arises over which courses will be listed as fulfilling general education requirements and which courses will be required for the completion of a major and what majors should be offered. The logic here is obvious. The more programs in which a given course is listed for credit the larger number of students who will potentially enroll in the course when it is offered. The larger the enrollment the more frequently the course can be offered to meet the demand. The more sections of a course needed to meet the demand the more staff needed to teach the course regularly. The more staff needed to teach the course regularly the easier it is to justify the request for additional permanent staff. The larger the permanent staff the more diversity possible in representing different areas in the

discipline or the easier it is to have more than one specialist in a given area in the discipline making more community and collegial exchange possible. In order to profit from a curriculum revision, a sociology department would probably have to form an alliance with other departments who would boost the cause of sociology courses in return for sociology faculty lobbying and for votes for the allied department's courses.

In the last major curriculum revision at the University of Tennessee, two years (or intermediate competence) in a foreign language became a requirement of all degree programs in the College of Arts and Sciences. For several years this change created a staffing boom in terms of new positions in the language departments at the school. A similar thing happened in the English department where a year of English composition became a university-wide degree requirement. What is "just" here is determined by which majority prevails in the revision of general education and requirements for majors. Justice for all in the sense of an equal opportunity to attract students is not likely to have much of a following in curriculum debates.

Sociology does have a unique contribution to make to general education. Few people seem to be commenting on this fact today.

One of the most eloquent statements about the contributions of sociology to a general education has been made by Robert Bierstedt (1964). He details seven ways in which sociology as a discipline contributes to the making of an educated person:

> Like history in particular, the study of sociology liberates the student from the provincialisms of time, place, and circumstance and frees him from the constrictions of his natal culture. Secondly, it introduces him to the role of logic and of scientific method in the acquisition of knowledge and thus contributes thirdly, to this sense of order and to his methodological sophistication. In the fourth place, sociology is a discipline that spans two cultures, the scientific and the humanistic, using as it does the method of science to explore the concerns and affairs of humanity. In the next instance, the fifth, . . . sociology initiates and keeps at the front of student awareness the ancient problem of the relationship between society and the individual (1964:54). As a sixth point . . . sociology is not content with description, however thorough it may be, or with analysis, however profound. It has a more fundamental quest. It seeks also the causes of things — things as they are and as they have come to be. (51)

Finally Bierstedt argues that (with some unfortunate exceptions) sociologists write with good and sometimes striking literary quality.

Space will not permit elaboration of these points. Throughout my career I have heard many discussions of sociology and sociologists from those outside the field condemning us for poor scientific method, for poor writing, for provincial and biased teaching. These criticisms are not supported by the evidence. But our silence in the face of the criticism expresses our tacit agreement that our colleagues do not do the best they know. The critics receive our support whenever we tolerate less than the best writing and most careful investigation in ourselves and in our students. Further, the attacks on sociology are justified when we too easily succumb to accepted stereotypes and generalizations rather than challenging them.

Teaching sociology demands our best. Doing research in sociology demands our best. Because we are participants in the societies and cultures that we study

we are constantly in danger of importing the values and the perspectives of that society and the subcultures in which we participate into our teaching and research. Sociology is not chemistry. We often interact with those we study and whose behavior we teach. Even when we do not interact we bring opinions about them into our research and teaching about these extraordinary groups. Those in other disciplines recognize this danger; they aren't stupid. They recognize that sociology walks a narrow line between informing and advocating. When we advocate to the point that we only narrowly inform — we cross the line from being educators to propagandists for the American life or some other way of life, as we see it.

Justice and Sociology's Contribution to America's Social Policy

The above definition of *justice* referred to the widely discussed books, *Habits of the Heart,* and its follow-up volume, *The Good Society* (Bellah et al. 1985, 1991). At the end of the first chapter in *Habits of the Heart,* the authors state the problem of guiding social policy in American society:

> We need to reach common understandings about distributive justice — an appropriate sharing of economic resources — which must in turn be based on conceptions of a substantively just society. Unfortunately, our available moral traditions do not give us nearly as many resources for thinking about distributive justice as about procedural justice and even fewer for thinking about substantive justice. (26)

As noted earlier, Bellah and his team ground their approach to substantive justice in ideas derived from the Judaeo-Christian tradition. Early thinkers such as Jefferson recognized a fundamental contradiction between the value, "justice for all," and American institutions. In Jefferson's inaugural address, he called for "equal and exact justice to all men of whatever state or persuasion, religious or political." While he certainly believed in the procedural justice of our legal system, he could not forget that there is a higher justice that sits in judgment over human justice: "the laws of nature and of nature's God." In considering the continued existence of slavery, Jefferson wrote, "Indeed I tremble for my country when I reflect that God is just; that his justice cannot sleep forever." The profound contradiction of a people fighting for its freedom while subjecting another to slavery was not lost on Jefferson and gave rise to anxiety for our future if this contradiction were not solved (Bellah et al. 1985:31).

In *The Good Society,* the argument is developed that calls Americans to sacrifice, to reform institutions of international finance, to recognize worldwide interdependence (Bellah et al. 1991:243-50).

In an unpublished paper on the topic of environmental justice, I argue that one of the problems with sociological approaches to the environment is a failure to consider the moral significance of the interpretation that past or future generations might place on the use of a particular resource (Hood 1994). Does a particular tree by virtue of the contribution it makes to the beauty of a particular location have a value that transcends the value it would have if cut down and converted into so many board feet of lumber of a particular quality and other wood products? How does an individual compare the aesthetic value and the value in use as lumber? "Justice for all" must include not only those

human beings who are alive now — but, as Edmund Burke would say, those who were living in the past and those who are yet to be born (Burke [1790] 1955:110).[4]

Two other American authors coming from different perspectives have made recent conspicuous pleas for a more inclusive definition of "justice for all." From the political economy perspective, Horowitz in his recent *The Decomposition of Sociology* examines "policy research in a post-sociological environment" (1993:169-82). Horowitz uses the petroleum and energy crises of the 1970s and the Gulf war of the early 1990s, the drug policies and "wars" of the 1980s, and the AIDS epidemic to illustrate issues confronting the U.S. government that break down the familiar and long held pattern of distinguishing between domestic policy and foreign policy. After adding space exploration and environmental considerations to his list, he cites the annual report of the Research Triangle Institute as organized into functional categories rather than five disciplines that have contributed to social research. (Program evaluation research, population and family studies, alcohol and drug abuse, criminal behavior, mental health problems, hazardous-waste management policy, natural-resource damage assessment, risk management, energy resource planning, and market assessment and forecasting are the categories rather than psychology, sociology, economics, political science, and anthropology.)

Horowitz (1993) suggests that:

> We are at the dawn of a new era of unitary policy-making; and we need to reconsider organizational frameworks inherited from a past in which the dichotomy of the national and the international still made some sense. Clearly, the velocity of change, the shrinkage in measuring distances between places, and the shared physical as well as social environment make all past paradigms obsolete. The realities of social research and policy have already transcended old boundaries; only the forms remain to be changed. (178)

Albert Gore Jr. (1993) examines imperatives for international institution building in his examination of the implications of environmental policies in *Earth in the Balance*. Gore speaking as an observer of the world scene suggests that most countries in the world have made three important choices: "first, that democracy will be the preferred form of political organization on this planet; second, that modified free markets will be the preferred form of economic organization; and third, that most individuals now feel themselves to be part of a truly global civilization" (298). Noting the need to recognize the diversity among nation states in any plan to respond to a global environmental crisis, Gore ([1992] 1993) proposes a global Marshall Plan with five major goals:

> 1. Stabilizing of the world population.
>
> 2. The rapid creation and development of environmentally appropriate technologies.
>
> 3. A comprehensive and ubiquitous change in the economic "rules of the road" by which we measure the impact of our decisions on the environment.
>
> 4. The negotiation and approval of a new generation of international agreements.
>
> 5. The establishment of a cooperative plan for educating the world's citizens about our global environment. (305-306)

Gore advocates an overall purpose in establishing the plan of "the establishment, especially in the developing world — of the social and political conditions most conducive to the emergence of sustainable societies — such as social justice (including equitable patterns of land ownership); a commitment to human rights; adequate nutrition, health care, and shelter; high literacy rates; and greater political freedom, participation and accountability" (307).

These thinkers have converged on a central point of policy: (1) American social policy today has international or global consequences; (2) Justice, particularly substantive justice, requires that Americans re-evaluate their position of privilege within the world system. If I read these authors correctly, each of them suggests that we have a need to re-evaluate our own standard of living in terms of the consequences that the maintenance of that standard of living has for the planet. Paul and Anne Ehrlich (1988) compare families in various countries in the world They point out that an average American family affects the environment 40 times more than a family in India and 100 times more than one in Kenya. They continue:

> Conveniences taken for granted by the average American are impossibly beyond the reach of most Kenyan or Indian households — items such as cars, televisions, refrigerators, dishwashers, ranges, air conditioners, and numerous small appliances. The same applies to the dazzling variety of food found in ordinary American supermarkets.
>
> The Brogans' [the name of the American family described] vehicles, two of 180 million cars and trucks in this mobile society, illustrate the culture's demands on resources and the environment. The metals in the vehicles are nonrenewable resources won from their ores with much use of energy and a variety of environmental costs: air pollution emitted at mine and smelter and destruction of ecosystems at the mine site from building roads and dumping overburden. A long list of side effect flows from a vehicle's use: the environmental costs of petroleum extraction, refining, and transport; the pollution and ecosystem destruction from building roads, bridges, parking garages, shopping centers, gas stations; and exhausts that contribute to eye irritation, emphysema, and lung cancer, as well as to acid rain and the greenhouse effect. (938)

Some Personal Conclusions

During my preparation of this article I believe that I learned the following things about *justice*. Whether these have been satisfactorily demonstrated by the excavation of the literature that I have done, I leave to your judgment.

1. Justice is a value widely seen as important in American society and grounded in the Judaeo-Christian religious traditions that have influenced many American organizations and practices.

2. Justice is a property of a relationship.[5] Like love it is particularistic rather than universalistic. Justice is felt; it has both a cognitive and emotional dimension to its existence. This complicates generalizations about justice and raises questions about its epistemological status. This relational quality of justice reveals some of the strengths that newer, more observational methodologies have brought to the discipline of sociology.

3. Justice is practiced within the context of a value system of a particular culture. The notion that justice is blind to individual differences and particular circumstances is directly contrary to the proposition of cultural relativism which suggests that all values

(desires) are learned (embedded) in the value systems of particular societies or subcultures with those societies.

4. Justice requires that we consider the impact of our decisions not just on our own lives but on societies and cultures one third or one half way around the world. Justice is a relational concept and we now understand and affirm the right of not just other species of plants and animals to exist but the right of many cultures to exist. This consideration may mean the creation of new institutions that redefine the meaning of all and the meaning of common good.

In sum my view of American sociology is as a prophetic form of consciousness, struggling for a methodology and strongly committed to the proposition that all human beings are created to live free of social institutions that prevent them from reaching whatever genetic potential they have. I close with a quote from *Slim's Table.* "When we stop trying to feel good about ourselves, or to increase our own power by asserting our innocence, we can begin to look for answers by searching for truth" (Duneier 1992:168).[6]

Notes

1. Hegtvedt and Markovsky's (1995) article provides a concise discussion of various conceptions of justice in the sociological and social psychological literature. Of particular note is the following paragraph:

Social psychological definitions of justice typically refer to particular distribution rules: proportionality (equity), equality of outcomes or opportunity, or distribution according to needs. Cohen and Greenburg (1982) define distributive justice as 'the application of a normative rule to the allocation of resources to recipients' (p. 1). Justice exists when there is congruence between expectations for outcomes based on the normative rule and actual outcomes. What is normative, however, depends on perceptual, interpersonal, and situational factors. Recognition of incongruence between the rule and reality rests on similar factors. Thus, despite explicit definitions such as Cohen and Greenberg's determining what is just remains a relatively subjective process. (259)

2. The very famous passage appears at the beginning of Book VII of *The Republic.* While it is too long to reproduce here, the position revealed should be reviewed as a corrective to the stark empiricism that has dominated much American sociological thought.

3. Bourdieu (1993) offers an example as follows:

A simple example will make this clear: The sociology of religion may amount to research for pastoral purposes that takes as its objects laymen, the social determinants of church-going or abstention; it then becomes a kind of market research making it possible to rationalize sacerdotal strategies for the sale of the goods of 'salvation'. Alternatively it may aim to understand the functioning of the religious field, of which the laity is only one aspect, studying for example the functioning of the Church, the strategies through which it reproduces itself and perpetuates its power — strategies that include sociological studies (initially carried out by a canon). (13)

4. The specific quote from Burke ([1790] 1955) concerns the nature of society:

Society is a permanent contract. . . . It is to be looked on with other reverence, because it is not a partnership in things subservient only to the gross animal existence of a temporary and perishable nature. It is a partnership in all science; a partnership in all art; a partnership in every virtue and in all perfection. As the ends of such a partnership cannot be obtained in many generations, it becames a partnership not only between those who are living, but between those who are living, those who are dead, and those who are to be born. (110)

5. This is exactly the problem. Justice for all implies that each person will be treated as an end and not as a means following Kant's categorical imperative. This means that the distinction between universalism and particularism breaks down and it is difficult for the actor to transcend the limits of a specific relationship.

Parsons and Shils (1962) put it as follows:

The dilemma of transcendence versus immanence. In confronting any situation, the actor faces the dilemma whether to treat the objects in the situation in accordance with a general norm covering *all* objects in that class or whether to treat them in accordance with their standing in some particular relationship to him or his collectivity, independently of the objects' subsumibility under a general norm. This dilemma can be resolved by giving primacy to norms or value standards which are maximally generalized and which have a basis of validity transcending *any* specific system of relationships in which ego is involved, or by giving primacy to value standards which allot priority to standards *integral* to the *particular* relationship system in which the actor is involved with the object. (81-82)

6. The full context of this comment comes on the page before.

Unlike many Americans, the men at Slim's table are beyond believing in the possibility of racial innocence. . . . They see their communities coming apart and believe that more important battles must be waged at this time. They speak candidly about conditions in the ghetto and the wider society. This makes them different from many politicians, journalists, professors, and middle-class blacks and whites who place a higher premium on portraying their own "essential goodness in relation to others" than in searching for truth (Duneier 1992:167).

Sex and Race Homogeneity in Naturally Occurring Groups*

BRUCE H. MAYHEW, *University of South Carolina*
J. MILLER MCPHERSON, *University of Arizona*
THOMAS ROTOLO, *Washington State University*
LYNN SMITH-LOVIN, *University of Arizona*

Abstract

We generate a number of hypotheses about face-to-face groups using the energy distribution principle: the frequency of an event is inversely related to the amount of energy expended in that event. The principle predicts that (1) the size of groups will be inversely related to the frequency of their occurrence; (2) at any group size, the composition of social positions will be less heterogeneous than chance; and, (3) as group size increases, observed compositional homogeneity will decline at a slower rate than chance. We test these hypotheses using data on more than 100,000 naturally occurring, public, face-to-face groups gathered in sampling sweeps through two communities over a three-year period. The data support the hypotheses and yield interesting differences in the strength of sex and race heterogeneity. We discuss the findings as they relate to the general energy distribution principle and to other sociological perspectives.

We begin with a general principle drawn from the field of thermodynamics called the *energy distribution principle.*[1] This principle is expected to hold in any system where the total amount of energy does not change markedly during a

** Bruce H. Mayhew died on 3 March, 1988, after a two-year battle with cancer. He had collected all the data analyzed in this article and written most of the theoretical argument at the time of his death. The remaining three authors, representing two successive generations influenced by him, have attempted to analyze the data, report the results, and draw conclusions from them in a manner consistent with the quality and character of Mayhew's thought. (It is typical of his confidence and foresight that he had already drafted parts of the conclusions section, assuming that his theoretical ideas would be supported by the forthcoming data analyses; therefore, even these parts of the article bear his imprint.) We intend this article as a tribute to his remarkable intelligence and as an additional contribution of his unique perspective on sociology. Since Bruce did not have the opportunity to complete his thinking about the project and to view the results of the data analyses before completing this article, the remaining three authors are, of course, responsible for any shortcomings of the current version.* *Direct correspondence to J.  Social Forces, September 1995, 74(1):15-52

specified time interval, e.g., one day, one week, one year, etc. Given this condition, or a reasonable approximation thereto, the principle states that:

The frequency of an event is inversely related to the amount of energy expended in that event.

That is, if we observe a large number of events of type X, and if there is variation in the amount of energy expended in these events, then we hypothesize that a relatively large number of these events will involve relatively small energy expenditures and a relatively small number of these events will involve relatively large energy expenditures.

To take an example outside of sociology, consider the frequency distribution of earthquakes, classified according to the amount of energy in each earthquake as measured on the Richter scale. For the earth's crust within a time interval of one year, we find the general principle holds: large earthquakes occur infrequently, small earthquakes occur often.

Before turning directly to sociological substance, we need to be clear about relevant background conditions. We said that in order for the energy distribution principle to hold, the total amount of energy in the system should not change over the time interval studied. Or, at least, the amount of energy should be approximately constant over that interval. Is this true of events occurring in the earth's biosphere?[2]

To know whether there is significant variation in the amount of energy in the earth's biosphere in an interval of time chosen for study, we need to know whether the amount of energy emitted by the sun is variable or constant. That is, the vast majority of all energy in the biosphere comes from the sun. Although it was not known with any degree of certainty until as recently as 1973, variation in the amount of energy emitted by the sun is usually less than 1% (see Frazier 1982). And, since a variation of as much as 2% would precipitate an ecological catastrophe of biblical magnitude, we can be reasonably certain — from the fact that at least a few representatives of the human species are still alive — that no such event has occurred in recorded history. In any case, with the amount of energy pouring out from the sun varying less than 1% per year, it is reasonable to say on the basis of present evidence that the amount of energy in the earth's biosphere changes hardly at all over the course of a year. Accordingly, the energy distribution principle should apply to events in the earth's biosphere for an interval of one day, one week, one month, or one year.

Even if the total amount of energy entering the earth's biosphere does not change very much in one year, it is nevertheless true that the energy distribution over that biosphere is quite uneven (for details, see Schneider & Londer 1984:189-204). There are sudden, localized energy shifts in the form of earthquakes, volcanic eruptions, tornadoes, etc. These are clearly devastating to local populations, disrupting and even destroying whole communities. That these localized disasters are the exception, rather than the rule, permits social life to flow on and permits us to speak of the routine of everyday life. That routine would be impossible in the environment of frequent, sharp shifts in the energy level. Finally, the amount of energy flowing through human communities varies from one locality to another; large cities (through both their population and technology) harness larger amount of energy than do small towns.[3] What

matters for us is the relative infrequency of disasters and the relative stability of the energy level in each human community. If we are willing to assume that the routine we see is an indirect indication of highly stable energy levels, we can apply our energy distribution principle to most human communities, most of the time, and encourage students of disasters to fill in the gaps.[4] Without denying that disasters may have considerable relevance to the operation of human social systems, we shift to questions of more immediate sociological concern.

Our objective throughout will be to indicate how our energy distribution principle applies to each type of event discussed. First, we must establish clearly the scope of the principle's application. We are attracted to the principle because of its extreme generality: it describes the distribution of all events, both physical and social. We need to make clear, however, that it applies only to *events*. Sociologists often find themselves studying the characteristics of individuals rather than social forms (for more on this distinction see Mayhew 1980, 1981; Simmel 1894). People are not events, however. Individuals do not expend energy; their activities (social and nonsocial) do.[5] It is the distribution of activities, especially of social activities that create observable social forms, to which the sociologist will apply our principle.

As with any social form, measurement of events and their energy expenditure can be difficult. Part of the reason that sociologists so often study individuals rather than social phenomena is that they appear well-bounded, vivid, and easy to measure using conventional survey technology (Mayhew 1980, 1981; McPherson 1982). The boundaries of events can be somewhat difficult to determine (see our discussion in the Measurement section), but this problem is not unique to social phenomena. The boundaries of hurricanes and other lesser storms are ambiguous, but we can measure their energy expenditure by the millibars of pressure at their center (the lower the pressure, the more powerful the storm). Similarly, voluntary associations may have an amorphous membership that makes their size difficult to determine. However, we find that multiple measures of the size concept (such as an officer's report, a member's report, and an actual count of one meeting's attendance) all converge on a common value (McPherson & Rotolo 1995). While boundary and energy measurement issues may be complex for social phenomena, we argue that consistent definitions developed and applied to a particular domain of events are possible and are preferable to the alternative of restricting our study to individual characteristics. We now illustrate our thinking with the application of the energy distribution principle to a domain of social interaction.

The Size Distribution of Face-to-Face Groups

Consider the size distribution of face-to-face groups that may be observed in public places. Size refers to the number of people in the group. And, although groups are by definition never smaller than two persons, we will admit a more general distribution of *aggregates* that includes size one: a single individual appearing in public alone. If we are willing to assume that the number of people in an aggregate (group) is a rough measure of the amount of energy

being expended by the group, application of our principle is relatively easy in this case. That is, we would predict that aggregates of size one will occur most often, that aggregates of size two will occur less often, and that the largest groups will rarely be seen.[6]

Before passing beyond this case, let us note exactly how it is reasonable to equate the number of persons in an aggregate with increasing energy expenditures. If a single individual goes out into a public place — perhaps on the way to a movie or to go shopping — she or he expends energy walking, driving, or even just sitting or standing. Now, for aggregates of size two or larger, an additional consideration comes into play. As we choose to observe only those aggregates (of size two or larger) that are engaged in face-to-face interaction (rather than just being physically proximate), the energy expenditure for these larger aggregates will be compounded by the addition of each person not only because more individuals require more energy to operate as biological organisms, but also because they are engaged in social communication to maintain coordination of their actions (in shopping, attending a movie, going to lunch, etc.). This means that energy must be expended not only on going out in public (as would be true for any lone individual), but also on coordinating action to carry out the activity in which the group is engaged. Any cooperative effort requires that individuals transmit signals to one another, that each monitors the signals and behaviors of the others, and that each attempts to align his or her actions with those of the others in the group. Thus an excursion in a group increases each person's energy expenditure by virtue of the constant checking of signals among persons.[7] And, the larger the group becomes, the larger the number of others one has to monitor and coordinate action with. Hence, the energy expenditure would increase multiplicatively, rather than in simple arithmetic fashion.[8]

We do not argue, of course, that size (or its multiplicative function) is a perfect measure of energy expenditure. Two people of different physique and different rates of metabolism may not expend *exactly* the same amount of energy even though they are engaged in identical activities (e.g., walking, talking). Each dyad in a large face-to-face group may interact less intensively than the single dyad in a group of size two. In very large gatherings, a division of labor may occur that lessens energy expenditures.[9]

Before leaving the case of face-to-face groups and their energy expenditures, we wish to emphasize one point. We do not wish to imply that individuals *choose* to travel alone in public because it is more energy efficient. The energy distribution principle does not depend on a mechanism of human choice; if it did, it could not apply effectively to physical phenomena like earthquakes and storms. Rather, it is a general law or principle that describes the distribution of any domain of events that fit the conditions described in our initial statement.[10]

Social Interaction and Physical Distance[11]

Physical distance has generally been considered to regulate social contact because of the amount of energy that must be expended to overcome the friction of space. Longer distances require more energy, shorter distances

require less energy. Hence the distribution of interaction events is expected to follow our energy distribution principle: interactions over short distances (requiring small energy expenditures) will occur often, while interactions over long distances (requiring large energy expenditures) will occur much less often. This observation has been so well documented that Mayhew and Levinger (1976) have called it the "law of distance interaction," which states that "the likelihood of interaction or contact of any kind between two social elements is a multiplicatively decreasing function of the distance between them, or of the costs of overcoming that distance"[12] (93).

Note that in this argument, physical distance is used as a proxy for energy expenditure. As with group size, distance is likely to be an imperfect measure. When technology reduces the energy expenditure necessary for communication over longer distances, physical distance becomes a poorer measure (as when it takes less energy to call someone in Singapore than to contact someone next door who has no telephone service). If technology produces enough disturbance in the system that physical distance is no longer a reasonable proxy for energy expenditure, we might have to restrict the domain that could be studied with this proxy to face-to-face interaction. Notice that Mayhew and Levinger (1976) anticipated this qualification by explicitly including energy expenditures in their statement of the law of distance interaction. They note that changes in the "level of contact technology" will result in step-function effects in reducing the impact of distance on interaction (see also Hawley 1971). However, they argue that increases in technology have never reduced the effects of distance to zero in any society, and that therefore, the law of distance interaction should hold *ceteris paribus*. Here, we merely note that this law is a special case of our energy distribution principle and hence is subsumed under it.

Language and Social Interaction[13]

While not all contacts between humans involve information transfer in symbolic form (Mayhew 1984a), a great deal of what we call social interaction does involve such transfers through codes (natural languages) that have evolved over relatively long periods of time.[14] Furthermore, the amount of time and energy required to learn one of these codes is considerable. Hence, we expect that most people would learn only one or at most a very few such codes. Most people are monolingual. And, to the extent that communication requires a common code, language differences represent a barrier to communication, while language similarities provide low-energy opportunities for contact. It requires less energy to communicate with those who speak our own language, and much energy to communicate (or in any way coordinate action) with those who speak a different language. The more similar two languages are, the less energy required to overcome communication difficulties, and the less similar two languages are, the greater the amount of energy required to execute any kind of contact or coordination in interaction. So, the tendency of people to communicate most often with persons sharing the same language and less often with those who speak a different one is a special case of our energy distribution principle.

Social Interaction and Social Distance

One hypothesis that has developed in the sociological literature over many years might be called the social distance interaction hypothesis. It claims that

> The frequency with which people enter into face-to-face association (contact, interaction) is inversely related to the social distance between them.[15]

This homophily of social contact is one of the best-supported empirical generalizations in the sociological literature. Researchers have found homophily in all age groups (from schoolchildren to the elderly). It occurs on many dimensions, including basic sociodemographic characteristics such as age and sex; acquired characteristics such as education, prestige, and social class; personal attributes such as attitudes, beliefs, and social behavior (see a review of this voluminous literature in McPherson & Smith-Lovin 1987). Far from being a matter of individual choice, the increasing frequency of association between similar others often has structural sources (Blau 1977; McPherson & Smith-Lovin 1982, 1986, 1987).

In this article, we define social distance as any *difference* in social position. These include differences in age, sex, occupation, race, ethnicity, rank on wealth, rank on power, rank on prestige, years of education, and membership in any of a wide variety of social groups including families, organizations, etc.[16] All of these are social positions. If two individuals occupy the same position on a given dimension (e.g., sex), the social distance between them is zero on that dimension. If two individuals occupy different positions on the same dimension (e.g., wealth), then there is a nonzero social distance between them, although how we choose to measure that distance may vary according to a variety of theoretical rationales. At a minimum we can say that social distance can take on values of *zero* (when two people occupy the same position) and *one* (when two people occupy different positions). Hence, the social distance interaction hypothesis can always be tested at this minimal level of measurement.

If we identify a dimension called *sex*, with categories male and female, and another dimension called *race*, with categories African American and white, we can suggest a measurement extension for social distance, a measure that simply adds up the social differences in question. Thus for persons who interact with those like themselves, interaction is occurring across social distance zero. For persons who interact with others differing on only one dimension, interaction is occurring across social distance one, and for persons who interact with others differing from themselves on two dimensions, interaction is occurring across social distance two. Clearly, as long as we stay with two-category dimensions, the social distance scale can be indefinitely extended beyond these scores by adding new dimensions (e.g., age: old, young; wealth: rich, poor; power: strong, weak, etc.). It is important to realize that this illustration is a direct extension of the reasoning employed in our more elementary measure mentioned above. That is, if sex and race are social dimensions and their categories of male-female and African-American–white are different positions, we have in this extension merely operated on our original assertion that there is social distance between persons occupying different social positions. Again, with appropriate theoretical rationales, still different and even more refined measures can be suggested.[17]

Now that we have made clear (we hope) just what is meant by social distance, the social distance interaction hypothesis should be sufficiently clear to permit addressing the issue: Is this hypothesis a special case of the energy distribution principle? The answer is yes, and the reasons for this answer are outlined in the following paragraphs.

Humans are biological organisms that expend energy in overt and covert activity (covert activity refers to electrochemical energy expended in the central nervous system). Humans are allocated to different social categories (positions) that structure the experiences of their entire life courses, that is, that determine what they will learn and experience in social life. Their central nervous systems encode social information of various kinds, including behavioral programs associated with (1) their own social categories (male, white, young, attorney) and to a lesser degree (in some cases amounting to nearly zero) with (2) other social categories (opposite sex, different racial or ethnic groups, different age groups, different occupations, etc.). When humans form groups, the activity that occurs there requires the expenditure of overt and covert energy, especially in any case where joint action of members is required (to go on a shopping trip in a public place, etc.). Since humans have encoded more information about their own categories' expected behaviors, more time and energy must be expended in heterogeneous groups just checking signals for action (see Carley & Palmquist 1992). This time and energy expenditure diverts time and energy from the conduct of external joint operations (going shopping). So humans will in all sizes of groups (two and larger) form associations that are disproportionately homogeneous with respect to social position than would be expected by chance. People will associate most often with others like themselves because doing so decreases energy expenditures. People will associate least often with others different from themselves because doing so increases energy expenditures. If this is so, the social distance interaction hypothesis is a special case of the energy distribution principle.

The argument we have outlined for social distance may be amplified by recalling our discussion of natural languages. In effect, we have been saying that when people are socialized into their social positions, they learn a language (code) peculiar to those positions. The network ties that define their position lead to shared knowledge, a subcultural code, with others to whom they are tied (Carley 1991). While these languages are a part of the subculture of each position, rather than natural languages strictly defined, their effect is the same: they pose an *energy barrier* to communication. Just as it is difficult (requires great energy expenditure) to communicate or in any way coordinate action with others who speak a different natural language, so it is difficult (requires great energy expenditure) to communicate with persons who have learned the language of positional subcultures other than our own.[18] So, while speaking the same natural language (e.g., English), the subcultural language of an African American female attorney and the subcultural language of a white male dishwasher are sufficiently alien in the grammar of actions and expectations they permit that they constitute energy barriers to communication and coordinated action. We are saying that each position has its own code (language), that covert and overt actions are structured differently for different positions so that the social distances between them are virtually identical in form (if not in

strength) to the natural language barriers discussed earlier. Hence, the same energy argument applies, and, of course, the same deduction is appropriate: interaction regulated by social distance is a special case of the energy distribution principle. People will be observed in face-to-face associations with others like themselves quite often because less energy expenditure is required to sustain communication and coordinate action. People will be observed in face-to-face interaction with others unlike themselves only very rarely because more energy expenditure is required to sustain communication and coordinate action. At all sizes of face-to-face groups, there will be a bias toward positional homogeneity of the participants.

Heterogeneity in Face-to-Face Groups

We have already said that the size distribution (even including aggregates of size one) of face-to-face groups is a phenomenon we wish to understand. And we have claimed that at all sizes of face-to-face groups, there will be a bias toward homogeneity that may vary as a function of group size. That is, even if there is a general bias toward homogeneity at all sizes, this in no way excludes the possibility that homogeneity-heterogeneity may show systematic variation as a function of size.

If each increment in size places an added energy burden on communication between group members, as we have argued, then any increase in heterogeneity with size, or even the same level of heterogeneity at larger sizes, would compound the difficulties in communication and coordination of action. Therefore, we expect that the multiplicatively increasing relational coordination demands of larger groups will lead positional homogeneity to increase at an increasing rate with group size.

Hypotheses

Although we have discussed a variety of issues, only a few lend themselves to direct tests on groups observed in public places. We shall examine the following hypotheses:

Hypothesis 1. The size of groups (including aggregates of size one) will be inversely related to the frequency of their occurrence.

Hypothesis 2. In any size of group, the composition of social positions will be less heterogeneous than chance.

Hypothesis 3. Homogeneity will increase at an increasing rate with group size.

These hypotheses are made for face-to-face groups observed in public places. This domain satisfies the scope conditions of the energy distribution principle: it deals with *events* for which we can observe reasonable (if imperfect) measures of energy expenditure — the size distribution and heterogeneity of the groups.

Data Collection

"Each discipline tends to develop a distinctive way of characterizing the problems it confronts — its own paradigm or world view. Fields vary also with respect to the forms in which their typical data are observed, measured and recorded" (Freeman 1984:346). While Freeman's statement is certainly correct, there are also some similarities in the problems confronted by different fields of study. Marine biologists studying hammerhead sharks in oceans and sociologists studying face-to-face groups in public places share the difficulty of identifying the population from which a sample can be drawn. There is no known population of hammerhead sharks in the oceans and there is no known population of face-to-face groups in human communities. So both marine biologists and sociologists are forced to adopt a procedure of making "sweeps" through areas where they suspect they may find "representative" cases. The rationale for this procedure (aside from lack of choice) is that after a large number of studies have been conducted by different investigators in different locations, the total amount of data collected and analyzed in all the studies will approximate — rather than completely misrepresent — a reasonable sample from the universe of cases. On this optimistic note, we turn to our data collection procedures.

SITE CHARACTERISTICS

Two towns in South Carolina were selected for making observational sweeps. The first, Winnsboro, is a small town that serves as both a market and an administrative center for Fairfield County. Winnsboro is the county seat and occupies a central geographic location in the county. Fairfield County is extremely rural, with about 80% of its land area in forests and fields. Winnsboro is the largest population concentration in this county; in 1980 Winnsboro's town limits contained 2,919 people, although local government authorities estimate that Winnsboro and its immediate environs has a population of around 8,800 people (Green 1985). The entire population of Fairfield County was 20,700 people in 1980. The second town, Columbia, is the state's largest city, the state capital, and the county seat of Richland County. Columbia is the central city of a two-county SMSA consisting of Richland and Lexington counties. Our observations for Columbia were confined to its urbanized area within Richland County. Within its city limits, Columbia had a population of 101,208 people in 1980, while Richland County had a total of 269,735. The entire metropolitan area (Richland and Lexington counties) had a total population of 410,088 in 1980.

There are two principal highways linking Winnsboro and Columbia. The first separates them by 29 miles, the second by 34 miles. The northern part of Richland County, which forms its border with Fairfield County, resembles Fairfield County generally in being composed primarily of forests and fields. Consequently, there is a rural region approximately 20-25 miles wide separating Columbia and Winnsboro. The two towns are quite distinct populations separated by a wide rural space.

OBSERVATIONS

In each town, observations were conducted between October 1979 and August 1982. The observation periods, or "sweeps," were carried out for each morning and afternoon for each day of the week in both towns. This sequence was repeated four times, producing a total of 56 data sets for each town ($2 \times 7 \times 4 = 56$) for a total of 112 observation periods. Most sweeps represent a two-hour observation period. The number of observational sweeps were balanced by month of the year, as well as day of the week. In Winnsboro the observations were made by sweeping through the entire town and also in one shopping center located approximately one-half mile from the town limits. In Columbia the vast majority of the observations were made in a 52-block area comprising the principal business district, the state capitol and office buildings, and a large university; at the state fair grounds (located within the city limits), and at two large shopping malls located outside the city limits but within the urbanized area.

During a typical observation period an observer walked or drove from one location to another. The observer stopped periodically at street corners and made an observational sweep noting the number of groups (including one-person aggregates) and the sexual and racial composition of each aggregate. The observer then moved on to another location. These steps were repeated over a period of two hours. In making observational sweeps, the observer made an effort to distinguish actual face-to-face groups from persons who just happened to be standing close to one another. In a large number of cases (about half), this presented no problem because many groups arrived on the scene together in a car.[19] In other instances, the observer made an effort to ensure that the people were actually talking together before including them in the observation set. Also, to minimize errors, the observer confined observations to those collections of people within 20 meters of the observer.[20]

Results

Two outcomes of our observations in Columbia and Winnsboro require emphasis. First, for every observation period all categories of persons (white male, white female, African American male, and African American female) were present in the observation area and appear in each data set. Second, every type of dyadic (or pairwise) interaction within and across social categories was observed at one time or another in both towns. Thus, Blau's (1977) two axioms, that people interact with others like themselves and that people interact with others different from themselves, are empirically correct for the two towns.

METHODS AND RESULTS FOR HYPOTHESIS 1

Hypothesis 1 predicts that the occurrence of groups will be inversely related to size. The frequency distributions for the size of the naturally occurring groups for Columbia and Winnsboro are shown in Table 1.

As one can easily see, the peak of the distribution for both the towns occurs at size one. As size increases, the distribution shows a sharp decline. This

TABLE 1: Frequency Distribution of Group Size by Town[a]

Size	Winnsboro Frequency	Columbia Frequency
1	24,839	43,799
2	10,630	16,347

[a] Data gathered by observation in a total of 56 random sweeps of each town, balanced by month of the year and day of the week. See further information in text.

decline is emphasized by observing that more than 94% of the groups observed in Columbia and Winnsboro were of size three or less. Hence, as this table illustrates, the size distribution of aggregates in both towns conforms to the prediction of hypothesis 1.

Because our test of hypothesis 1 is based on the analysis of human groups, which are subject to constraints of coordination among the members of the group, we can make more specific predictions than simply that the observed frequency is a declining function of group size. Recall that the basic argument for this hypothesis is that the maintenance of the increasing number of dyadic relationships embedded in a group increases multiplicatively, rather than additively, as size increases. As we have discussed elsewhere (Mayhew & Levinger 1976:93-94), the potential number of contacts in an aggregate depends upon both the maximum possible number of contacts (the number of possible dyadic relations) and the underlying contact distribution (how many contacts each point or person has). In very large aggregates (e.g., cities or societies), we must make assumptions about the contact distribution in order to estimate the density of interaction — what Durkheim (1893:283) called "dynamic density" (see the discussion in Mayhew & Levinger 1976:94). But for small face-to-face groups, it is reasonable to assume that contact is often saturated and that most of the maximum potential number of contacts (or relations) are activated. To the extent that this assumption is not met, using the maximum potential number of contacts as a baseline model for the number of contacts in the group and our more specific version of hypothesis 1 developed below will overestimate the increasing rate at which size will affect energy expenditure. Since this question is an empirical one, we proceed with our development of a formal baseline with which to compare our frequency observations.[21]

Formally, the number of dyadic relations in a group of size S is:

$$D_s = \binom{S}{2} = \frac{S(S-1)}{2} = \frac{1}{2}S^2 - \frac{1}{2}S \quad (1)$$

where S is the size of the group and D_s is the number of embedded dyads. Values of D_s and S are presented, along with a graph of the structure of dyadic relationships, in Figure 1. As the figure shows, D_s is an increasing quadratic function of S. As the number of people in the group increases, the number of dyadic relationships in the group increases nearly as half the square of group size. According to the energy distribution principle, a given group will be constrained by the coordination effort captured by equation 1, as well as by the necessary energy expenditures for maintenance and transport of each individual in the group (see the discussion in an earlier section). We don't expect that the relationship in equation 1 will be mirrored exactly in the data, since probably not all possible dyads in the group will be activated for larger groups in a given time frame. What we expect is that the observed curve will be a member of the family of curves that increase quadratically; the curve should accelerate. Thus, we do not argue that the distribution of group size will exactly mirror the function described in equation 1 (that is, the coefficients will not exactly equal ½), but it should have the same general form. We can write equation 1 in the form of a regression model of counts:

$$N_s = \alpha + \beta_1(Size) + \beta_2(Size^2) + \gamma \quad (2)$$

where N_s is the number of groups of size S, and α, β_1, and β_2 are parameters to be estimated from our data. The qualitative prediction for equation 2 we derive from hypothesis 1 as interpreted by equation 1 is $\beta_1 < 0$ and $\beta_2 > 0$. These predictions follow from the signs of the coefficients of S and S^2 in equation 1. When $\beta_1 < 0$ and $\beta_2 > 0$, size and frequency are related multiplicatively according to the general form of equation 1. We estimate the parameters in equation 2 with negative binomial regression analysis.[22] As Table 2 shows, this hypothesis is generally supported. Although the coefficient for $size^2$ is not significant in Winnsboro, all coefficients are in the predicted direction. The results strongly argue that the general relationship between group size and frequency of occurrence is of the multiplicative form predicted by our elaboration of hypothesis 1. Not only is frequency of occurrence a strongly decreasing function of group size ($\beta_1 < 0$), but the exact shape of the curve relating size and frequency is consistent with the idea that the number of embedded dyads in the group adds to the energy expenditure necessary to coordinate the group ($\beta_1 < 0$ and $\beta_2 > 0$).

METHODS AND RESULTS FOR HYPOTHESIS 2

Hypothesis 2 states that conditioning on group size, the composition of social positions will be less heterogeneous (i.e., more homogeneous) than chance for any group of at least size 2. A test of this hypothesis requires that we calculate the expected number of homogeneous groups under random expectation for the two types of social composition in both towns. In other words, we require a baseline to compare with our observed results (Mayhew 1984a). This baseline will show what random associations of individuals would produce and allow us

FIGURE 1: The Number of Dyads Embedded in Groups of Increasing Size

Size (S)	D_s (Number of embedded dyads)	Structure of dyadic relations
2	1	
3	3	4	6	5	10	N	N(N-1)/2	—

to ascertain what systematic sociological forces (such as the energy distribution principle) might be operating to produce deviations from a random assortment of individuals.

To obtain the baseline expectation, we use the definition of the expected value of a random variable. We calculate the probability of a homogeneous group for a group at each size, where size varies from 2 to 11 (the observed maximum size in our data). Since the social composition variables sex and race are both binary response variables, the binomial distribution governs the probability of a homogeneous group of size S forming under random expectation.

In order to understand why the binomial distribution is the correct baseline, it is helpful to recall how the binomial distribution can be used to calculate expected values for the familiar experiment of tossing a coin n times (where $n = 1, \ldots N$). Consider the experiment of flipping a coin three times. We know p = Pr(Head) = 0.5 and q = Pr(Tail) = $(1 - p)$ = 0.5. Hence in order to calculate the probability of either exactly three heads (e.g., corresponding to a homogeneous group of three males) or exactly three tails (e.g., a group of three females, we compute

$$Pr(3\ Heads\ or\ 3\ Tails) = (0.5)^3 + (0.5)^3 = 0.25$$

The situation for our research problem is similar to that of the coin-tossing experiment. In our case, the size of the group under the random baseline is analogous to the number of coin flips. However, we cannot simply assume that the probabilities of the binary response for either race or sex are one-half, since the total number of people with a given social composition differs for each town. For example, the towns are not composed of a population of exactly 50% male and 50% female. Instead we use the observed proportions for each social composition variable. For instance, for sex homogeneity, we determine the proportion p of females in each city by pooling all our group observations for that city.[23] Then we can define $q = (1 - p)$, where q is the proportion of males in each city. These proportions represent the probability of encountering a female or male in the public places of each town. Similar proportions can be calculated for race homogeneity in each town. From this information and the frequency values in Table 1, we can determine the probability of observing homogeneous groups under random expectation at each group size. The expected number of homogenous groups at each size is

$$E(Homogenous\ group_i) = n_i Pr(Homogenous\ group_i) \qquad (3)$$

where n_i = total number of groups observed at group size i ($i = 2, \ldots 11$).

Hypothesis 2 predicts that the composition of social positions will be more homogeneous than chance. The results for hypothesis 2 are shown in Table 3.

As these tables show, for any group, the observed number of homogeneous groups is larger than the expected number under the baseline model. Groups in both communities are more homogeneous with respect to sex and race than would be expected by chance.

To illustrate this fact concretely, let us examine the racial composition of large groups in Winnsboro (shown in the first panel of Table 3). Given the roughly 50-50 representation of African Americans and whites in the communi-

[a] γ is a stochastic component that accounts for possible overdispersion in event count data.
[b] Parameter estimates for size and size^2 were calculated using the negative binomial regression method in COUNT (King 1989a). Standard errors for the estimates are in parentheses.

ty (see note 24), it would be extremely unlikely that a large group would not include at least one person of each race if the energy distribution principle were not in effect. Indeed, the baseline model predicts that we would be unlikely to see even one group larger than size 7 that was homogeneous on race; the expected value for a group of size 8 or larger is .37 (adding .30, .05, .02, and .00). Such groups should be extremely rare by chance. But our data show that 53 such racially homogeneous groups are observed, where none (or at most one) would have been expected. Therefore, we believe some sociological principle (such as the energy distribution principle) to be in operation.

METHODS AND RESULTS FOR HYPOTHESIS 3

Our test of hypothesis 3 uses the same baseline model as in hypothesis 2 in order to test the proposition that compositional homogeneity will decline at a slower rate than baseline expectations. We use the same binomial distribution to plot the probability of group homogeneity as a function of size and then determine the rate at which the function declines. Similarly, we model the observed probability of compositional homogeneity as a function of size and determine its rate of decline.

TABLE 3: Number of Homogeneous Groups for Winnsboro and Columbia: Observed vs. Expected

[b] Expected number of groups under binomial baseline from equation 3.
[c] Sum of number of sexually homogeneous groups (either all male or all female) at each group size.
[d] Expected number of groups under binomial baseline from equation 3.

Since compositional homogeneity is a binary response (homogeneous group = 0; heterogeneous group = 1), we use a logit model of proportions (the continuous analogue to the discrete binomial in Table 2) to estimate the rate of decline of homogeneity with size. The model for the decline in homogeneity is the logit model (Hosmer & Lemeshow 1989):

$$\frac{1}{\left(1 + e^{-(\alpha + \beta * SIZE)}\right)} \tag{4}$$

Parameter estimates for the rates of decline for each of the four models are shown in Table 4. The estimates can be interpreted as the log odds of encountering a homogeneous group as compared to viewing a heterogeneous group in the data. In all models, the parameter estimate for size is negative and highly significant, indicating that as size increases the odds of observing a homogenous group decrease as compared to a heterogeneous group.

Figures 2-5 show graphical representations of the rates of decline in the probability of compositional homogeneity by social composition in both towns.

All four figures show conclusively that the observed probability of a homogeneous group declines more slowly than the expected rate under the baseline model, strongly supporting hypothesis 3. The results are significant beyond the 0.001 level. The formal tests of the differences, based on a nonlinear estimation routine in SAS PROC NLIN (SAS/STAT User's Guide 1989), are

*** $p = .0001$

presented in Table 5. These tests compare the rate of decline in observed compositional homogeneity to the rate predicted by the baseline model.

In all four cases, the *t*-statistic is extremely large, indicating that there is a significant difference between the observed rate of decline and the rate of decline under random expectation. The observed probability of a homogenous group declines much more slowly than the model of random expectation predicts, strongly supporting hypothesis 3.

A SUPPLEMENTARY FINDING

As may been seen in Tables 4 and 5 and Figures 2-5, the bias toward homogeneity at all sizes of groups is more pronounced for race than for sex. This is especially true for Winnsboro, where the difference between expected and observed homogeneity decline is the largest that we observe (see column 3 of Table 5). We did not hypothesize this outcome in advance, but we interpret this result as being consistent with the energy distribution principle on at least two grounds. First, this result might mean that the subcultural codes of racial groups are more different than are the subcultural codes of the sexes. If so, it means that there are, by our reasoning, greater energy barriers to communication between African Americans and whites than between males and females on language (subcultural code) grounds alone.

We might expect such a situation if race is more correlated with other dimensions than sex. Blau (1977), for example, has pointed out that nominal categories such as male and female, or African American and white, may derive their primary social significance from the fact that they are highly correlated with other social dimensions. In particular, they may be highly correlated with material wealth or income. Blau suggested that a great deal of the difference in social position for African Americans and whites may derive from their

Race homogeneity	-.259	-.611	.352	10.97	< .001

[a] The observed rate of decline (b) was estimated with SAS Proc Logistic and the expected rate of decline (β) was estimated with SAS Proc NLIN. In all cases the t-statistic indicates that the observed rate of decline is significantly less that the expected rate of decline, supporting hypothesis 3.

differential rank on the dimension of income.[24] In the U.S., whites have higher rank (status) on median income than African Americans, and men earn more income than women. If this income difference is an extremely powerful factor in determining the life chances of persons in different positions — as Blau clearly believed — then such differences as we may observe for sex and race could easily be a function of their (median) income position and the life experiences that it shapes. These effects of income on life experiences (and therefore on subcultural codes) will be stronger for race than sex, if we consider that income is often translated into consumption and other experiences in household units. Men and women in the same household may share these experiences to some degree;[25] households, of course, tend to be quite homogeneous with regard to race. If income can have an impact on social interaction, or is in any way highly correlated with other position dimensions, greater observed effects for race as compared with sex may be operating primarily through rank (status) on income (material resources). This interpretation would allow us to generate hypotheses about regional differences that we would expect if our study in replicated in nonsouthern regions. To the extent that the American South has a higher correlation between race and other social positions, we would predict that the relative effects of race and sex would be more equal in other regions. In areas with more middle-class African Americans who are more widely spread through occupational, religious and voluntary systems, we would expect to find the subcultural codes of African Americans and whites to be more similar. The sex-heterogeneity of households probably will lead race to be more important than sex in most contexts; however, the relative size of the distance should decrease to the extent that whites and

African Americans occupy similar social positions. Informal observations in Arizona support this prediction.

A second factor also may be important in the relative weighting of race and sex in our analyses. It will be noted that, whereas the sexes are sprinkled relatively uniformly across virtually all residential areas, African Americans and whites are not.[26] The higher degree of residential segregation on race means that African Americans and whites are physically separated by greater distance that are the sexes. Hence, the law of distance interaction (a special case of the energy distribution principle) predicts that group homogeneity on race will be greater than group homogeneity on sex. This second argument presupposes that many of the groups we see go out into public have begun their journey at home and so may be composed of members of the same household or immediate neighbors. Both arguments may be correct: language and subcultural code differences between people are commonly a function of the physical distance separating them (Mayhew 1984b).

Notice that our argument about residential segregation by race would elaborate and qualify our discussion of regional differences above. Since the South (especially in smaller towns and cities) generally has somewhat lower levels of racial residential segregation than other regions, the law of distance interaction would lead us to expect a relatively *smaller* effect of race in the South than in other regions. A more complete analysis would take into account *both* the level of positional racial segregation (e.g., in occupations and income) and the level of residential segregation. The dramatic differences between the expected and observed homogeneity in Figures 2 and 4 may be an indication that the subcultural variation created by positional segregation may be a more potent force than the physical variation created by residential segregation. A systematic study that included variation in these factors and that observed groups in neighborhoods as well as central locations would be necessary to test this hypothesis.

Since such a study is not yet available, we continue our discussion of the logical implications of the hypotheses. If our arguments are correct, we also have a (post hoc) interpretation for the city differences that appear in Tables 4 and 5. Because of its rural, heavily agricultural character, Winnsboro and surrounding Fairfield County have a much greater correlation between race and other positional characteristics than exists in Columbia and its SMSA. In Fairfield County, most African Americans live in rural communities, working in either the logging industry or low-paying service jobs, or supported by social welfare programs. Whites are more likely to live in town, work at local small manufacturing plants, or occupy professional service jobs. While the differences between the races in Columbia also are dramatic, they are muted by the presence of state government, a major university, and the military; all these institutions create in-migration from outside the South and tend to be more egalitarian in their hiring than more traditional, local organizations. Given these factors, we believe that the subcultural and physical distances between the races are greater in Winnsboro than in Columbia, leading to our observation that racial homogeneity is more pronounced (as a declining function of size) than is sex homogeneity.

Some Implications

The energy distribution principle has served as the basis for deriving a number of predictions about face-to-face social contacts among humans. Only a few of these were translated into predictions about associations in face-to-face groups in public places, but the hypotheses so obtained were all confirmed in the research reported here. Now that we have at least one such confirmation, it is appropriate to summarize the general argument we have made. The law of distance interaction, the tendency of people to interact primarily within their own language group, and the social distance interaction hypothesis are all subsumed under the energy distribution principle. These, in turn, produce two of our hypotheses; the first hypothesis derives directly from the energy distribution principle. Finally, our finding that homogeneity is greater on the dimension of race than on the dimension of sex follows from the law of distance interaction.

ALTERNATIVE EXPLANATIONS FOR FREQUENCY AND HOMOGENEITY

For each of the three hypotheses that we have discussed, earlier researchers have proposed alternative interpretations. However, proposals that offer a different explanation for each hypothesis would be inferior to any proposition (such as the energy distribution principle) that subsumes all three interpretations. Furthermore, some alternatives are more apparent than real: there are many propositions that can be translated into energy distribution terms. We now turn briefly to some of those alternative explanations and show how they relate to our arguments.

Several models have been constructed to predict the *shape* of the group (aggregate) size distribution (cf. Cohen 1971; Coleman 1962; Coleman & James 1961; Goodman 1964; White 1962). For example, Coleman and James (1961; Coleman 1962) developed a mathematical model that argues that the rate of people joining and leaving a group is determined by the density of contacts within a closed system (i.e., a multiplicative function of the number of isolates and the number of groups). White (1962) used assumptions from queuing theory to develop alternative models with varying assumptions about the probability of joining and leaving groups. He dealt with both open and closed systems, and developed a model (the gamma model) in which the rate of joining and leaving depended on the number rather than density of isolates. All these models are based on the opportunity structure of contacts within the system and they predict the general functional form of the size distribution that we observe.

All these models are consistent with the energy distribution principle. They do not, therefore, constitute alternatives to hypothesis 1. Since they are structural explanations, based on the opportunities afforded by the distribution of contacts within the system, they are analogous to the physical theories that explain how chance configurations of weather patterns come together to form storms of various intensities. The important point is that the series of events (in our case, joining and leaving events) that will result in a large group will be rarer than the series of events that will lead a person to stay an isolate or to join

a smaller group. We also note that while these explanations provide an interpretation for the size distribution (hypothesis 1), they are silent on the homogeneity predictions of hypothesis 2 and hypothesis 3. The energy distribution principle is therefore to be preferred on the basis of both generality and parsimony.

Another class of theories that might speak to the size of human groups focuses on economies of scale and the supposed efficiencies that come from coordinating efforts among differentiated components (Smith 1791). A naive (and easily falsified) prediction from this division of labor — efficiency argument would be that large groups should be more common than individuals and small groups. A more sophisticated version of the argument would tie the size distribution to the goal of the group and the tasks being performed in the groups. Even if we assume that appearing in public places can subsume a wide variety of goals, this economic framework would have to posit a complex distribution of goals and tasks to explain the observed distributions of group size. In particular, the economy-of-scale argument would not predict the specific functional forms of our hypothesis 2 and hypothesis 3 predictions: why would tasks or goals be so arrayed as to produce economies in exactly this form? Since the energy distribution principle can predict the observed distributions with a single, extremely general law, it is preferable on those grounds.

Issues of homogeneity and heterogeneity (our hypothesis 2 and hypothesis 3) are often addressed by affective or cognitive theories in social psychology. These theories posit that people are more likely to be attracted to those who are similar to them on virtually any characteristic, including sociodemographic characteristics, achieved statuses, attitudes, or beliefs (e.g., see McPherson & Smith-Lovin 1987:370).

Cognitive theorists also have dealt with similarity issues. People are more likely to choose to associate with similar others as the result of social comparison processes (Festinger 1954). If people in public places were motivated to assess their own behavior for its appropriateness, these comparison processes could explain the homogeneity in our groups. If we are willing to make the further assumption that behavior appropriateness becomes a more salient issue if the group is larger, then this approach might even explain the tendency of our groups to get more homogeneous (relative to chance expectations) as they become larger. Modern cognitive theorists argue that the cognitive complexity of the knowledge associated with a domain influences the latency (processing time) for responding to stimuli in that domain (Eysenck 1984). If we assume that stereotypes of racial groups are not as clear in individuals' minds as gender stereotypes, or if individuals tended to have more counterexamples to racial categorization than to gender categorization, this greater cognitive complexity could explain our result that race homogeneity differs more from our baseline model than does sex homogeneity. These arguments obviously lack the power and generality of the energy distribution principle but might be interpreted as special cases in the following sense.

The affective theories that explain attraction can be translated into cognitive theories that focus on information load. People "like" things that are familiar, that require little processing load, and that allow a predictable environment. They "prefer" others whose positions and characteristics are similar enough to

make a reasonable basis for self-comparison and self-evaluation. All this may be summarized efficiently by stating that people like those who may be expected to have similar knowledge bases and cognitive structures (Carley & Palmquist 1992). Further, we believe that the cognitive arguments are consistent with and can be subsumed under the energy distribution principle. As we elaborated above in our discussion of natural languages and subcultural differences, more energy is required to decode and encode interactions with those who are different from us. The latency measure used by cognitive psychologists is explicitly interpreted as such: the longer the latency, the more cognitive network links must be traversed and the more processing energy used to decode a stimulus and encode a response to it. Therefore, the cognitive processing (and the affective affiliations that it generates) are special cases of our principle. Furthermore, we note that the affective and cognitive theories do not produce an explanation for the frequency distribution in hypothesis 1 (although the cognitive processing arguments might predict that the processing load would go up with the number of coordinating dyads — a prediction that elaborates our principle).

Explicitly structural theories that predict homogeneity in groups are Blau's work on inequality and heterogeneity (Blau 1977; Blau & Schwartz 1984), Skvoretz' (1983) elaboration of that work, and McPherson's (1983, 1990; McPherson & Smith-Lovin 1986, 1987) ecology of affiliation. Both Blau and Skvoretz take homophily as a primitive assumption in their theories (Blau calls it "salience," Skvoretz calls it "tau-bias") and predict that the heterogeneity of groups will result from this bias and from the opportunity structure afforded by the distribution of people in categories (male vs. female, white vs. African American). Note that this demographic opportunity structure is what provides us with the baseline to which we compare our observed homogeneity (see discussion above and Figures 2-5). The energy distribution principle makes predictions about the deviations from this baseline, or the homophily principle that Blau and Skvoretz use as their unanalyzed assumption.

McPherson's (1983) theory takes a similar tack, and argues that much of the observed homophily in affiliation choices is due to the opportunity structure created by the groups within which these choices are made. Note that this argument is consistent with the energy distribution principle on all fronts: (1) aggregates formed from previously existing collectivities will take less coordination energy than aggregates that form from previously unaffiliated actors; (2) these previously existing affiliations will have been shaped by our principle in the sense that homophilous organizations will find coordination and control of activities easier to manage and will therefore be more likely to survive, and (3) choices made within the opportunity structure of previous affiliation will still display greater homogeneity than chance (as observed by McPherson & Smith-Lovin 1987) because of the cognitive and affective dynamics discussed above as special cases of the principle.

GENERAL ALTERNATIVE THEORIES: SPACE, TIME, AND ENERGY

Under certain circumstances, arguments that rely upon variables mapped on space, time, or energy can be translated into one another, e.g., Stephan (1979). Stephan and McMullin (1981) have suggested that their time-minimization theory in sociology may play a role similar to that of the principle of energy-minimization in physics or cost-minimization in economics. We applaud the efforts of those like Stephan and his colleagues. We have no objection at all to attempts to formulate a theory of social organization around the idea of time-minimization, including in that enterprise the translation of spatial and energy arguments into time arguments. However, we think care should be exercised in making the translations. It should never be assumed that any energy argument, or any space argument, can just automatically be given a time interpretation. The same caution holds for attempts to convert other variables (space, time) into energy variables. When such translations are made, they should be spelled out carefully and with a view to enhancing our ability to systematize and generalize our knowledge. We assume that such care has been taken up to the present time, so our remarks are intended to apply to future attempts. It is entirely possible that a superior theory can be constructed for a wide range of social phenomena based on time-minimization alone. However, it is equally possible that a superior theory could be constructed from energy arguments alone. Our suspicion at the present time is that a superior theory is more likely to be a compound argument employing both time and energy variables.

ENERGY DISTRIBUTION AS A COVERING MECHANISM

As indicated by the discussion above, the energy distribution principle has the advantages that it can predict both (1) the frequency distribution of face-to-face groups and (2) the relative level and form of their homogeneity, relative to a reasonable baseline afforded by the demographic opportunity structure. It acts as a covering mechanism, encompassing a large number of interesting, useful theories that researchers have developed to describe one or more of these phenomena (see Mayhew 1984b:310-12 for a discussion of covering laws). In that sense, it does not refute these other theories. It offers a more general functional form of the relationships that they predict. We argue that these general statements of functional relationships (of the general form "A is a [specified] function of B," where both A and B are variables) are the appropriate goals for scientific theory (Mayhew 1984b:310-11). The specification of so-called causes that discuss unobservable mechanisms are not relevant to scientific discourse *unless* they can be translated into qualifications — further specifications — of relations among observables.

In other words, we have not proposed our energy distribution principle with a view to suggesting that it is either (1) true or (2) superior to other arguments that might be constructed. On the contrary, following Turner (1984), we challenge others to construct better theories, to improve, reject, or reformulate our arguments through research and improved theoretical statement. In the spirit of our belief that a theory should be judged by its correspondence with data and by its fruitfulness for prediction in a wide array of social domains, we

conclude with two applications of our energy distribution principle to substantive areas rather different from those that we have dealt with in this article. We propose these ideas as an encouragement for others to collect different types of data with which to test our ideas. Our ideas relate to the historicity of interactions and to stratification by income.

HISTORICITY

When we observe two people in social interaction, we may find upon inquiry that they have known each other for a long time, that they have a *history* of repeated interactions with one another. Clearly, we can divide interaction sequences (Collins 1967) into two broad categories: (1) those that are repeated interactions between two selected individuals and (2) those that happen for the first time between two selected individuals. The first are customarily conceived — when repeated sufficiently often — as leading to primary group (personal) relations, while the second are relegated to secondary group (impersonal) relations.

When we observe interaction sequences that repeatedly pair the same two individuals, we are seeing the operation of the energy distribution principle. The more frequently two individuals have interacted with one another in the past, the more they share information in general, and the more they share information about one another in particular (Carley 1991). That is, the two individuals are in the process of learning one another's subcultural codes (position language). If the two people occupy nearly identical social positions, the amount of learning of a different subcultural code is at a virtual minimum. If the two people differ on one or more characteristics, then repeated interactions permit them to become familiar with the other's position code, *so that* the amount of energy expended in interaction steadily decreases over time as interactions are repeated. The more the two people learn one another's language, the less energy each needs to expend to communicate with the coordinate action with the other. Thus, regardless of how many interactions we see in a given population, when we partition these into (1) instances of repeated interactions between the same persons and (2) new interactions between two persons, we should observe that a given individual will be devoting most of his or her interaction time to repeated interactions (because these expend less energy per unit of time) and less of his or her interaction time to first-time (new) interactions (because these require greater energy expenditures per unit of time).

In fact, we can say that these episodes of repeated interactions between the same two persons constitute a special case of the "Axiom of Cumulative Inertia" (McGinnis 1968:716): The more often two people have interacted in the past, the greater is the probability that they will interact in the future. This is, of course, because such future interactions expend less energy than future interactions with new (unknown) others.[27] We can therefore develop a whole continuum for the interaction frequencies of each individual, based on the dyads in which she or he participates. For a particular individual A, we can say that A's interaction time will be distributed so that A interacts most often in dyads (triads, tetrads, etc.) containing others with whom A has most often interacted in the past, and

so that A interacts least often in dyads (triads, tetrads, etc.) containing others with whom A has interacted least often in the past. Thus, the energy distribution principle governs each individual's interaction-time distribution *in terms of which other individuals are involved in each time slot.*

This repeated interaction between persons, or *historicity,* emerges as a special case (or consequence) of the energy distribution principle along more than one path. Recall that the law of distance interaction is a special case of the energy distribution principle: people interact most often with others near to them in physical space and less often with those farther away. Furthermore, the movement of people across physical space is governed by the same principle (Zipf 1949). People move about in space (cover physical distance) frequently through short moves and only very infrequently through long moves. So consider each individual's stability-movement distribution. For moves of the individual across space (in the plane) over the times $t_0, t_1, t_2, t_3, \ldots, t_N$, we observe a random walk whose transition probabilities are given by a first order Markov chain: a random walk *biased* so that each move in space is governed by physical distance. That is, each move has a higher probability of being over a small distance than over a long distance. When this process is visualized for an entire population perambulating along random walks in physical distance (in the plane), we find that at t_N each individual has not moved very far from his or her original position at t_0.[28] This means that *most individuals are highly stable in physical space.* And the indicated stability means that the randomly selected individual will be in the same geographic locale most of the time. Hence, each individual will be close to others who also do not venture far from the same locale most of the time. And because people interact most often with those near in physical space, each individual will be in interaction with the *same* other persons most of the time, i.e., those others who also occupy that individual's locale. Accordingly, historicity appears to be, at least in part, a consequence of the energy distribution principle through the law of distance interaction.[29]

STRATIFICATION

An increase in positional homogeneity as a function of group size could clearly come about in more than one way. In our hypothesis 2 and hypothesis 3 we have discussed the pressures toward homogeneity as a result of the energy expenditure required for coordination among group members. We made no predictions about the *content* of the groups, that is, what types of people will be found in groups (aggregates) of size one, two, and so forth. That heterogeneity in social positions would be expected to decline as a function of group size (partially) *through a bias in category composition* is predicted by our energy distribution principle through two lines of status argument.

First, people who are of high status on income tend to be more heterogeneous with respect to most other social characteristics (e.g., occupational position) than are people who are of low status on income.[30] This means that, when summing over all the social distances between them (on occupation, education, etc.), low-status persons are on the average closer to one another in social distance than are high-status persons. Hence, there are fewer (energy) barriers between low-status persons than there are between high-status persons.

The energy distribution principle predicts that the aforementioned size-heterogeneity relation we expect to observe will come about in part because of an increasing proportion of low-status individuals in larger groups. Concretely, relatively small groups (and aggregates of size one) will be disproportionately composed of high-income people; relatively large groups will be disproportionately composed of low-income people. Aggregates of size one are included in this generalization, of course, because high-status persons — being far from most other persons on most social dimensions — will have fewer similar persons to associate with. High-status persons would therefore appear in public alone at a higher base rate than low-status persons.

Second, a status argument can rest on the assumption that *money is an energy converter*. Concretely, in a money economy like that of the U.S., the more money one has, the more energy one can drain from the system (in the form of transport vehicles, gasoline, etc.). Money dissolves energy barriers that would otherwise block access to public places. Money controls differential opportunities for energy expenditures (Galaskiewicz 1979:1348). Accordingly, a deduction from the energy distribution principle is that the distribution of income across persons will be highly skewed such that a relatively small number of individuals will have large amounts of money and a relatively large number of individuals will have small amounts of money. That this is the case is well known.[31] To emphasize this point: the energy distribution principle predicts that any event that involves the expenditure of energy must conform to its shape. Since the distribution of money across persons is a measure of their differential opportunity to expend energy, the income distribution is merely a special case of the energy distribution principle. Economic resources must be expended (on transport, etc.) to go to public places. The lower the income status of people, the more likely they are to pool resources (money, cars, etc.) to go to public places. The higher the income status of people, the less dependent they are on others for economic resources: they are comparatively free to go to public places alone. Because low-status people often must pool resources to venture into public places and high-status people are not so constrained, high-status people should be disproportionately represented in small groups as well as in one-person aggregates; and low-status people should be disproportionately represented in large groups.

Whether from the first or the second line of status argument, we expect that the average status of group members will be a decreasing function of group size (including aggregates of size one). Both status arguments can easily be correct, with each contributing in some degree to the observed outcome. The first status argument refers to energy expended within the group in the process of social interaction itself. The second status argument refers to energy expended to go into public places (on transport, etc.). Thus, each focuses on a different energy event, but both predict the same outcome for group composition as a function of group size. It is important to bear in mind that the first status argument hinges on the assumption that high-status persons are (on the average) farther from one another on the social distance scale than are low-status persons; while the second status argument hinges on the assumption that money is an energy converter (or serves as a mechanism for converting information — the numerical value of each monetary unit — into energy).[32]

Summary

In this article, we have argued that the energy distribution principle can be applied to many domains of concern and can encompass many more specific models. We found empirical support for three predictions about the size and homogeneity of naturally forming face-to-face public groups. The energy distribution principle predicted not just the relationship between size, frequency, and homogeneity of groups, but also the functional form of those relationships. We closed with applications of our general principle to areas about which we do not have data at this point: the interaction histories of persons in groups and the income structure of groups. We hope that these ideas will stir others to apply the energy distribution principle to diverse domains of inquiry.

Notes

1. Jonathan Turner (1984) has suggested that sociologists might do well to abandon attempts to construct *a* theory or *the* theory for each of their respective domains of inquiry. Instead, he suggested, sociologists would benefit from concentrating on the development of *general principles,* principles sufficiently general that they may be applied to more than one domain of concern, e.g., to stratification, to group formation, to bureaucracy, to norm formation. The result of these attempts — if successful — would be a storehouse of general principles, an arsenal of ideas that sociologists could use to tackle almost any problem. Basically, Turner (1980), like Stephan (1979:821), has advocated a return to the strategy of Comte's social physics. See also Stewart (1948). While we do not here advocate abandoning attempts to construct theories about particular phenomena (such as stratification), Turner's general suggestion seems very reasonable to us and the present essay is an attempt to follow his advice.

2. One reader suggests that the energy distribution principle leads to implausible predictions such as cloudy days being more frequent than sunny days and that its scope should be limited only to social events. On the contrary, the principle is widely accepted as describing the operation of physical phenomena (Tribus & McIrvine 1971). It is our challenge here to argue for its applicability as a general, covering principle in the operation of social systems as well. The apparent implausibility of the sunny versus cloudy day prediction stems from the logical flaws in its derivation from the principle. Sunny and cloudy days, as events, do not entail differing amounts of energy; the amount of solar energy reaching the earth's surface during any 24-hour period is roughly constant. Weather events in a particular locale are created by heat transfers that result from upper-level wind and moisture flows. Only from the perspective of *an individual* at a particular place on the earth's surface does weather affect energy received. It is the event itself, not the individual's access to it, to which the energy distribution principle applies.

3. On the role of technology in creating different energy levels in human communities and societies, see Lenski and Lenski (1982) and White (1943). On energy flows created by different technologies, see Cook (1971), Kemp (1971), and Rappaport (1971).

4. Mayhew (1983:176-90) outlined a frame of reference for studying the impact of sharp shifts in energy level on human social organizations (more generally, see Kreps 1984 and references therein).

5. For example, one reader suggests that the principle would predict that babies would be more common than middle-aged people because they expend less energy. This prediction is not consistent with the principle, because the energy distribution principle applies to events rather than people.

6. This outcome has been observed in several studies (Cohen 1971; James 1951, 1953).

7. As Elijah Anderson (1990) describes vividly, people also can expend significant amounts of energy to *avoid* contact with one another. The most straightforward way to study this

phenomenon using the energy distribution principle would be to define a domain of avoidance events that could then be hypothesized to vary in frequency with the strength and difficulty (energy expenditure) of the avoidance. How would we expect avoidance to affect the energy expenditure of groups and its relationship to group size? If avoidance is a more salient issue for single individuals in public alone, the energy expenditure devoted to avoidance would reduce the effectiveness of group size as a measure of energy expenditure and would work against our hypotheses (discussed below). If avoidance energy expenditures increase with the boundary maintenance problems encountered by larger groups, then they will strengthen our use of group size as an indicator of energy expenditure. Clearly, we argue for the latter interpretation, which is simply a special case of the principle.

8. As we elaborate below, a multiplicative increase does not have to literally double or triple in effect with an addition to the group. What we argue is that the energy increase follows a quadratic function, specified later in equation 2.

9. A reader argues that increasing the division of labor would reverse this relationship. We argue that, on the contrary, the division of labor is at least partly a response to the energy distribution principle. As systems increase in size, the amount of energy expended in coordination would reach impossible levels without an increase in structure (Mayhew et al. 1972). By structure we mean some arrangement whereby not all possible connections in the system will occur. Whether this increase in structure takes the form of functional differentiation (Smith 1791), hierarchy (Mayhew 1983; Williamson 1975), or some other adaptation will be dictated by other considerations.

10. Notice that the domain must be defined to include all relevant events, rather than those within a limited energy or size range. For example, we would want to include all storms rather than just hurricanes, since hurricanes are storms reaching a certain minimum energy expenditure. If we study transportation events, we would not want to restrict our attention to buses or trains, since they are specifically designed for *mass* transit; instead, we would look at all instances of transportation. Then we would certainly find that people traveling alone (in cars or by foot) would be the most numerous category. Households are an interesting case. The modal household appears to hold two people (cf. Davis & Smith 1990). Frequencies above two show the pattern the principle would predict, but one-person households are slightly less common than two-person households. Is this a disconfirmation? First, we have to ask whether a household is an event. The more appropriate unit of analysis for testing the principle would be the actually occurring aggregate, rather than the officially defined household unit. In other words, a household is an event only when all its members are actually copresent and interacting. By this measure, the number of people who are "home alone" when contacted would doubtless push the number of one-person aggregates upward. In addition, we find that official statistics and common surveys define out of their population or fail to find many individuals who live as singletons: the institutionalized, the homeless, members of the armed forces, students, etc. If such cases were included, the modal category would certainly be one.

11. We will not be making direct tests of the relationship between physical distance and social interaction frequencies. Distance is discussed here as an item subsumed under the energy distribution principle because it enters into the interpretation of our results.

12. For references to research supporting this proposition, see the materials cited in Mayhew and Levinger (1976:93-94).

13. We will not be making a direct test of the impact of language on the frequency of social contact (but see Carley 1991). However, language differences at the level of subculture (including differences in dialects) enter into our reasoning about social distance. Hence, it is important to note that interaction frequencies across and within language groups are also a special case of our energy distribution principle.

14. We do not deny that people may communicate through "artificial" languages and through technologically enhanced channels (Kaufer & Carley 1993). However, since most artificial languages and augmented channels are in fact peculiar to certain subcultures, our subsequent discussion of sexual, ethnic, racial, occupational, and income subcultures permits us to include these artificial communication codes and channels in our arguments.

15. A narrower version of this hypothesis might be called the status distance interaction hypothesis. It claims that the frequency with which people enter into face-to-face association

(contact, interaction) is inversely related to the status distance between them. Because it refers to rank differences only, rather than to a more general difference in social position, this is a much narrower hypothesis than the social distance hypothesis discussed in the text. It becomes narrower still if status is further interpreted — as it usually is — to mean only rank on the vertical dimension of social approval (i.e., prestige, esteem, or social honor). Because some segments of the literature have managed to impose this narrower interpretation (Ellis 1956), a correction is required. In the present article, status refers to any *ranked social position* on any of the commonly used dimensions of vertical differentiation, especially including wealth, power, and prestige, but also including general indicators of these characteristics where appropriate (e.g., income, years of school completed). We have taken the time to specify this hypothesis because, while it is narrower than the social distance hypothesis, it may be that rank on vertical differentiation has more powerful effects than other kinds of social distance. If that is so, the status distance hypothesis is an extremely important special case of the social distance hypothesis, one that we need to keep clearly in mind when considering the relative explanatory power of different dimensions.

16. An objectivist definition of social distance is adopted here (cf. Blau 1977). In this external view, social distance is imposed (defined) by the outside observer. A subjectivist definition of social distance conceives of this dimension from the point of view of the individual observed (cf. Bogardus 1959). That is, social distance is given by the attitudes or feelings of individuals toward one another, and, consequently, may vary considerably from one individual to another. We do not consider the subjectivist approach here.

17. See the overview in Marsden and Laumann (1984:279-81). Extension of this idea to continuous variables appears in McPherson (1983) and McPherson, Popielarz, and Drobnic (1992).

18. This may seem much more obvious to the reader for some kinds of subcultural differences than for others, especially when differences are strong enough to take on the character of dialects within the same natural language. But we are arguing much more than this. We are saying that each position has its own subcultural code, that code being a variant on the common natural language spoken in a given society. According to Mannheim (1980), individuals who are classed together in the same concrete group share a basic stock of experiential contents. This could be true, of course, without requiring that these experiences constitute a distinct subcultural code. However, if we adopt Marx's (1939:80) view that language and thought are the same thing, then we would almost certainly require that people who occupy different positions do speak in different codes, even when they are using the same words in a natural language. To the extent that people occupy similar social positions, they experience many things in the same way *by virtue of that occupancy*. This increases the likelihood of contact or communication between them, because they speak the same language (think the same things, in Marx's view). The "contents of their consciousness are similar" (Vierkandt 1923:261-62). In stressing these similarities for people who occupy the same (or structurally equivalent) positions, we are not referring to the "pressures toward uniformity" in beliefs, actions, etc. that are commonly argued for people throughout the entire system (Allardt 1964). On the contrary, we are saying that this uniformity of experience, thought, and language is confined to particular positions within society. Those who remain skeptical that most social positions will have their own subcultural codes would do well to consult Bernstein (1960) and Schatzman and Strauss (1955) before prematurely rejecting our interpretation. For a more recent statement that appears to agree exactly with our argument, see McNall (1985:23). Simmel (1911:14) argued that people who are different from one another have difficulty in understanding one another.

19. One might raise the question of whether the fact that many groups arrived at the observational scene in cars could have constrained the size distribution; most cars can hold only two to four people comfortably. More generally, our observations of group size undoubtedly constrained by a large number of external social factors such as the size of households, the physical capacity of the setting to accommodate large groups, etc. We are encouraged by two features of this problem. First, in our empirical analyses we see strong relationships between group size and frequency (as predicted by our hypothesis hypothesis 1) both above and below the threshold that would be physically imposed by the capacity of the typical car (i.e., in the range 1-5 and in the range 5-11). Therefore, we are quite sure that the

strength of our relationship is not created by the transportation constraint. Second, the tests of hypothesis 2 and hypothesis 3 are not affected by any external constraint on group size. In general, we believe that the social constraints have evolved within the constraints of the energy distribution principle. We suspect that if people typically traveled in larger groups, transportation devices and public places would be designed to accommodate them (just as station wagons were more common when the average American family was larger). At any given point in time, however, these constraints shape the energy expenditure entailed by a given group size (e.g., it is more difficult to move a large group to a public event than a small group).

20. With respect to errors in observation, we assume that these will occur for any observation procedure that might be devised. Further, we doubt that two different observers — given the same location and time of day — would note exactly the same number of groups. We can only hope that over a large number of studies conducted by a large number of different observers, the errors will be small in number and random. Note that any tendency to notice systematically larger groups or groups of unusual composition will tend to work against our hypotheses. Therefore, we hope that our tests are conservative. All the data in the present study were collected by the first author.

21. One reviewer has suggested that we compare our size distribution of face-to-face groups with size distributions from other empirical settings (e.g., towns or firms). Such a comparison would bias the hypothesis test in our favor, since we believe that both empirical phenomena are generated by the same covering principle: the energy distribution principle. We prefer to use a baseline model that is clear in its assumptions (Mayhew 1984a) and that can be evaluated rigorously in terms of its accuracy in describing the data. While observing similarity of empirical distributions would pose an interesting question for future research (one that we trust would be answered through application of the energy distribution principle), such comparisons would be ad hoc in the sense that there would be no clear statement of the analytic principles that would generate such a distribution.

22. Negative binomial regression analysis can be regarded as a generalization of Poisson regression analysis, which parameterizes overdispersion in count data (see Barron 1992). We estimate the parameters of the models with King's COUNT procedure (King 1989a, 1989b).

23. We use pooled observations from our sweeps through public places rather than U.S. Census data to estimate the baseline proportions for several reasons. First, it is impossible to locate the boundaries of the population from which the face-to-face groups are being drawn. For example, Columbia's public may be drawn primarily from the city, its county (Richland County), or the two-county SMSA that constitutes its economic base (Richland and Lexington counties). The racial proportions would vary dramatically with the catchment area we assumed (from 39.7% to 38.2% to 28.5% African American, respectively). Similarly, Winnsboro is 50.5% African American, while Fairfield County is 57.6% African American. A second problem with using census figures for a baseline is the fact that the probability of a person appearing in public differs by race and sex. In both towns, African Americans are less likely to appear in public than their census populations would lead us to expect. In Winnsboro, 46.3% of people who appeared in our sweeps were African American; in Columbia, 31.5% were African American. Similarly, women are somewhat less likely than men to appear in public; women made up 46.3% and 54.2% of the publicly observed population in Winnsboro and Columbia respectively. These figures represent less than their census representation in both cases. We argue that social forces possibly related to energy distribution, such as residential distribution, availability of transportation, etc., create differences in public appearances.

24. Blau's terminology is in some instances different from our own; we mention these differences in order to avoid confusion. Blau uses the term *group* to include not only the traditional instance of people who are bound together in interaction, but also for social categories as traditionally defined (people with a common social position or characteristic, but without the implication that these individuals are in interaction with one another). Our use of *group*, especially face-to-face group, means exactly and only instances of people who are in direct face-to-face social contact with each other. At times we introduce the term *aggregate* to indicate that we are considering not only the size distribution of face-to-face groups, but also — added to these — aggregates of size one (lone individuals). Blau uses the term *parameter* for what we call a social dimension (age, sex, race, ethnicity). He distinguishes graduated parameters (age, income) from nominal parameters (sex, language group). Since graduated

parameters include our dimensions of vertical differentiation (status), they are quite important (in our view as well as Blau's). It is worth mentioning that our theoretical concerns are quite different from those addressed by Blau, although they overlap in some instances. Blau's theory is confined to dyadic contacts, whereas our concern is with face-to-face groups of all sizes, not just dyads. Thus, while most of Blau's theoretical concerns overlap ours, we have additional concerns (groups larger than two persons and, in some instances, aggregates of size one). Finally, our concerns are only with face-to-face interactions, whereas many of the contacts that can be subsumed under Blau's theory need not be restricted to face-to-face interaction.

25. We, of course, recognize that experiences in the workplace will differentiate high-income (on average) men from their lower-income (on average) wives. Also, power differences within the family created by relative income contributions of husband and wife may affect interaction patterns and create variations in gender-based subcultural codes.

26. Note that the major exception to this argument would be the army base at Fort Jackson in Columbia, South Carolina. We hypothesize that observations there might reverse the finding.

27. Simmel (1911:14) argued that we have less difficulty understanding a member of our own family (someone with whom we interact often) than we have understanding a stranger (someone with whom we have no past history of interaction).

28. Since a model of movement in the plane that permits each individual to select a direction of movement from each of 360 degrees, and then a distance to move in that selected direction, may seem unduly complicated for clear illustration in this simple discussion, more elementary models for such a random walk may be preferred. Following Eigen and Winkler (1975:50-52), we might construct such a walk on a board for a glass bead game, e.g., a checkerboard. Here, the individual is positioned in the middle of the checkerboard at t_0 and has five alternative transitions between $t - 1$ and t. She or he can (1) remain in her or his present position (the highest probability from the law of distance-interaction) or (2) move in any of four directions across the checkerboard, with the number of squares crossed in any move having transition probabilities that are a decreasing function of their distance from the individual's position at $t - 1$. A simpler model is obtained from a board with equilateral triangles; a more complex one from a board consisting of equilateral hexagons. From hexagons, we can move on to the more elaborate illustration with 360 rays out from the center of the plane.

29. Simmel (1898:667) said that the first thing determining the unity of human groups is spatial proximity of persons.

30. The argument is not that high status persons are farther apart on *all* position dimensions. (Indeed, there is some evidence from network studies that higher-status people have more system-spanning ties than low-status people.) Rather, they are farther apart on some *important* position dimensions. That some social categories that are low on income tend on the average to be more homogeneous on other social characteristics (such as occupation) has long been recognized. In the U.S., the case of African American females is particularly striking for occupational homogeneity (Blau 1977; Gross 1968). Incidentally, the dimension that determines status in this discussion — income — would itself be expected to show a greater dispersion of high-status persons: high-income persons (those above the median income) will be farther apart on income than will low-income persons (those below the median income).

31. Most income distributions approximate the lognormal distribution and therefore show a high degree of skew with a small number of high incomes and a large number of small incomes. See Champernowne (1973) and Zipf (1949) in general, and Atchinson and Brown (1957:107-20) in particular.

32. On the relationship between information and energy in this regard, see Tribus and McIrvine (1971). On the nature of money as a generalized resource in highly developed money economies, see Simmel (1900). On the conditions that give rise to money economies, see Elias (1939:61).

Emancipating Sociology: Postmodernism and Mainstream Sociological Practice*

JOEL SMITH, *Duke University*

Abstract

Using analyses of mass communication and research methodology, this article assesses the validity of the postmodernist critique for sociology. These analyses locate various weaknesses and inconsistencies in the critique. Three hypotheses are proposed to account for the tolerance the critique receives from many sociologists despite its recognized inadequacies. Some implications for the discipline of the factors involved in those hypotheses are discussed. The analysis concludes that sociologists are unduly tolerant of and responsive to such critiques.

Mainstream American sociology has long been a target of critical analyses — positivism, neo-Marxism, critical theory, ethnomethodology. The charges vary — sociology is not, cannot, and should not be value-free; it is inadequately scientific; it pretends to be scientific when, in fact, the relation of subjects to investigators makes that impossible; claims to objectivity are false; it should be explicitly political but is not; and so on. Postmodernism is the most recent of these critiques. Despite being of little interest to many American sociologists[1], it is inspiring a burgeoning sociological literature whose eventual impact on the discipline remains to be seen. It could be drastic. The unfettered observation, analysis, and interpretation that postmodernism has encouraged in the humanities may appeal to sociologists concerned with the historical specificity of and reflexive relationship with their material. That may account for the growing use of postmodernist rhetoric in sociological discourse.[2]

The critique draws upon the philosophy of language and science to assert that communication and perception must be flawed and unreliable. This implies

* *This is a drastic revision of an article prepared for a panel on Philosophical Foundations of Sociological Knowledge and Applied Sociology at the 31st Congress of the International Institute of Sociology, 21-25 June 1993. I have had the benefit of responses from William H. Form, Kenneth Land, Seymour Martin Lipset, John O'Neill, Herbert L. Smith, Edward Tiryakian, John Wilson, David Zaret, and three unusually patient and supportive anonymous referees. They identified numerous deficiencies, many of which I shall never be able to address adequately. However, I can and do thank them for their support and willingness to help. Direct correspondence to Joel Smith, Department of Sociology, Duke University, Durham, NC.*

that empirical inquiry is meaningful only to the investigator. If so, it would make no sense to share results because no one could be sure how others would take them. Research would be a selfish, ego-centered pursuit. If this is the prospect, sociologists need to assess the legitimacy and implications of the postmodernist critique for sociology. I do so from the perspective of my own work because a key postmodernist premise — it is impossible to validate interpretations of communication — and a key derivation from it — all methods of inquiry are warranted — appear to agree with positions I have taken. In this article I evaluate parallels between postmodernist analysis and my positions on (1) communication and (2) methodology. I also (3) propose several hypotheses that may account for why some sociologists have embraced and others tolerate the criticism and (4) discuss the implications for the discipline of the factors involved.

Postmodernism

The postmodernist analysis claims that there have been fundamental societal shifts resulting from transformations implicit in capitalism (see Smart 1992:141-82; 1993). Adherents vary on several matters that are not pertinent here[3], but basically they argue that the conditions of modern life altered as the consumerism fostered by capitalism and spread by modern media[4] — their role and weight is debated — transformed people's relations to one another and to their environments (e.g., virtual reality). This process, they claim, has resulted in the replacement of reality with various fictitious realities that cater to and preempt the attention of diverse new groups that transcend older social arrangements. The diversity of interests and activities separate the groups from each other. Change is now so incessant and rapid that there is no opportunity for a new societal integration. Consequently, for Baudrillard (1983:18), the possibility or desirability of social theory and the existence of "the social" are questionable (see Smart 1993:53).

Postmodernism is most widely espoused by scholars in the humanities (e.g., literary criticism, comparative literature, architecture), but its intellectual roots are in Nietzsche's critique of modernism. It has evolved through Heidegger to Barthes and Foucault, and uses "Wittgenstein and Gadamer for philosophical inspiration and . . . academic respectability" (Bauman 1992:40). Its assertions provide the basis for as radical a critique of the epistemology and ontology of positivistic social science as ever has been mounted. Rosenau predicts (1992:171), in understated prose, that, were skeptical postmodernism[5] to prevail, it probably would be mainstream empirical sociology's death knell.[6]

Lyotard (1984:79-82, 1989:7-10; also see Smart 1992:175-76) distinguishes three different connotations of the term, but is confident that there has been a major shift that is consequential for scholarship and knowledge (1984:3). Critics of postmodernism find it difficult to define (see Crook 1991:150; Bernstein, 1992:199-200; Rosenau 1992:7-19; Smart 1992:169-70). Rosenau notes that adherents disagree on its specifications, even debating the hyphen between "post" and "modern." Most writers describe postmodernism in terms of what it rejects. Aronowitz (1988) says it is "marked by the renunciation of foundation-

al thought, of rules governing art, and of the ideological 'master discourses' liberalism and Marxism" (46). Bauman (1992) says it is a reaction to a totalizing idea of reason, but not to rationality. The discussions converge on a conception of postmodernism as an antifoundational, antijustificatory, antirepresentational, critical deconstruction of tradition.[7] Rather than try to span the many differences among postmodernists with a definition, I use the term in this sense because it underlies their commentary on empirical social science.

Mass Communication

Postmodernists challenge the representative function of language (or in some cases anything) because connections between words and their referents are arbitrary and imprecise. Some claim that there is no social reality other than symbolic representations.[8] If so, anything perceivable is a potential symbol, and, hence, a text whose meaning, they argue, is indeterminate for several reasons.

1. Some texts were not produced intentionally, so their meanings only come from their perceivers.

2. The meanings of some intentionally produced texts never were clear because of various possible problems in their production.

3. Regardless of whether reason 1 or reason 2 applies, meanings at text reception can only be revealed in reports produced afterward; their connection to initial meanings is subject to the same uncertainty.

Consensual meanings, then, are unlikely or transitory because, other than by force, there is no way to establish and preserve them, particularly as what Lyotard calls the "metanarratives" of the past lose their force as computers change the nature of language and knowledge (1984:9-17,60-64,75-77). In view of these uncertainties, the possibility of communication and its role in ordering social behavior are always in doubt.[9] Indeed, some skeptics argue that "the social" may not exist and that society is a concept contrived to justify actions (e.g., training, coercion) that render people more controllable.[10] If so, sociology is a political project, not a scholarly discipline (Bogard [1990, 1992], however, suggests that Baudrillard and Lyotard simply consider sociology irrelevant). Aside from its political aspects, the issue of whether somewhat orderly and integrated social life is possible hinges on the issue of the meaning of symbols and the conclusions regarding consensual meanings and what follows from them.

Even though postmodernists may differ on whether a text can be anything (see Rosenau 1992:8), they agree that the most obvious texts are products of what most people consider communication — novels, poems, paintings, films, sitcoms, speeches, remarks, and the like. Inasmuch as the critique is particularly relevant to analyses of mass communication and mass media, it intersects with my interests. Long before these arguments were directed to the social sciences, students in my seminar on mass communication were questioning the precise nature of communication. In light of claims that the media both inform and manipulate, they insisted on the need to distinguish communication from influence. They argued that successful communication occurs only if intentional-

ly produced messages are received by targeted receivers who understand them as intended (see Smith, Bealer & Sim 1962:12). It follows that the criteria for successful communication must include a would-be communicator behaving as specified and receivers with mental states congruent with the intended meaning as a result of the action. Whether outcomes satisfy senders' desires to influence (or, in some cases, receivers' desires to be influenced) is irrelevant.

This concept of communication raises precisely the same problems noted by postmodernists.[11] To determine if communication is occurring requires knowing whom senders intended to reach, what meanings they intended them to have, who received these meanings, the meanings that intended receivers had after the act, and whether they were acquired from the act of reception. It is clear that several conditions make it impossible to access the data needed to be certain whether there is equivalence, and, if there is, whether it resulted from communication. It also is clear that no matter what evidence is adduced, there always will be uncertainty because, short of having reliable non-communication-based measures (e.g., brain activity) of what is happening at every moment with each participant for an indeterminate time span during which both learning and forgetting can occur, the only data on which to decide are reports subject to the same sources of inaccuracy.

Because human social life is so thoroughly involved with and dependent on communication, but neither subjects' reports nor analysts' interpretations of meaning can be validated, postmodernists argue that a social science that requires understanding actors' meanings is impossible. Several observations may be made in this regard. To accept them requires assuming the reality of everyday life, but this seems reasonable so long as postmodernists address others.

(1) Most sociologists assume that they interact with others, can observe others interacting, and that behavior called communication is one mode of contact. Because communication is fraught with error and experienced as risky and difficult, rules to address these difficulties develop in any group whose survival requires members to achieve and maintain shared understanding. The rules do not assure communication, but, in tandem with the bonds that lead people to attend to one another, they hold people together while they try to resolve the problems in sharing meanings. Moreover, motives that lead to an effort to communicate can be satisfied even if meanings are not shared precisely. Pure communication — completely congruent understandings as a result of intentionally transmitted messages — expedites but is not necessary for compatible social action. Most ongoing social relations, the requisite of social organization, can accommodate poorly articulated actions based on dissimilar understandings. Not only do most social relations *not* require perfect communication, this kind of communication could produce conflict.

(2) People are able to accept and take systems for granted in the same way. In analyzing the relation of social action to society, Schutz (1963) uses the postal service to show how trust facilitates the integrated, ongoing relations among strangers that make society possible. Even taken as a text, most people who use (i.e., readers) or work for the postal service (i.e., producers) "read" it similarly. Freedom to differ need not lead to disorder and unpredictability.

(3) Postal service also exemplifies the reality of social structure as a complex of persisting arrangements that transcend time, place, and individuals. There are many other cases of orderly social behavior based on assumptions (e.g., following the rules of the road, queuing up, paying taxes). Without immediate coercion and by relying on socialization through communication, activity among strangers is adequately coordinated and regularized to provide predictability in group life.

(4) The preceding observations imply that people are able to accept the apparent, the relative, the approximate, the taken for granted as real, a capacity captured in Thomas's (1951) famous dictum that "If men define situations as real, they are real in their consequences" (81). The inescapable uncertainties in everyday life that go with the mediation of people's access to reality is a crucial element in the postmodernist critique. However, mediation by the impedimenta of communication is not new.[12] Language alone always has mediated humans' relation to reality (see McLuhan 1964:81-84). Scientists proceed on assumptions and research accommodates indeterminacy — a concept originating in physics, not in social science. Postmodernists would deny social scientists the right to deal with uncertainty in the same way that most people, postmodernists included, do.

(5) Structured relations have effects without communication. The media, themselves, provide examples. New media have such characteristic effects as new consumption patterns for existing media, rescheduling and restructuring public events to meet media needs and schedules, and rearranging personal schedules to fit media schedules. Marshall McLuhan, an icon of many postmodernists, Harold Innis (1964), and others on whom McLuhan drew, note that, rather than destroy social organization, new media reshape it (see Meyrowitz 1985; Zaret 1992).

The assumptions that what is experienced as social reality exists and that people are able to act in an orderly manner on the basis of assumptions despite the uncertainty introduced by language run counter to central points in the postmodernist critique. Although many would demur, postmodernists' actions suggest that they accept these assumptions. It also is not clear that media-mediated reality creates fundamentally different problems from those that people always have faced in symbolically mediated environments. Agreement that an irreducible uncertainty pervades communication does not require accepting the conclusions that postmodernists reach. If people can live effectively with imperfect communication in mediated environments, sociological research with uncertainty should be possible. However, the inescapable problems attending the mediation of reality by symbols, and by reflexivity, are forceful reminders of its limits.

Methodology

The postmodernist analysis of communication undergirds its radical position on social research. "Some of the most important consequences of the postmodern revision of text, author, and reader are methodological in nature" (Rosenau 1992:40). In contrast to conventional social scientists, who "seek to isolate

elements, specify relationships, and formulate a synthesis . . . (postmodernists) offer indeterminacy rather than determinism, diversity rather than unity, difference rather than synthesis, complexity rather than simplification. They look to the unique rather than the general, to intertextual relations rather than causality, and to the unrepeatable rather than the re-occurring, the habitual, or the routine" (8). If this view prevails and if sociology is to continue to be relevant, it must "break its links with the ontological and epistemological premises of modernity . . . by accepting . . . the self-containment and self-grounding of the production and reproduction of meanings" (Bauman 1992:26). That would mean that sociologists could no longer treat social reality as an object and analyze data as if they shared concepts with consensual meanings. In turn, it would require fundamental changes in procedures and substance.

If, as postmodernists claim, it is impossible to validate any interpretation of a text, none are demonstrably right or wrong and all are equally plausible. Consequently, for postmodernists "social science becomes a more subjective and humble enterprise. . . . Truth gives way to tentativeness. Confidence in emotion replaces efforts at impartial observation. Relativism is preferred to objectivity, fragmentation to totalization" (Rosenau 1992:8). Moreover, those who argue that there is only representation and no reality admire (41) and even encourage the production of numerous, possibly inconsistent, interpretations (95, 134), none of which are to be privileged (119) (also see Lyotard 1984:44, 81).

Rosenau suggests that this is a reaction to social scientists' "uncritical confidence in modern science and smugness about objective knowledge . . . (They) are uneasy with their more conventional colleague's (*sic*) uncritical acceptance of philosophical foundationalism, the Enlightenment heritage, and the methodological suppositions of modern science. . . . Those applying the post-modernism of the humanities to the social sciences . . . seek to . . . undermine their foundational claims" (9). Emphasizing the importance of the rejection of language as representational (see Baudrillard 1988:77-78, 80-92), "hostility to representation is linked to the post-modern preference for soft rather than positivist epistemology, to its aversion to objectivity, and to its insistence that difference is more important than sameness. Antirepresentation leads postmodernists to criticize modern scientific epistemology for its materialist conception of reality, for its separation of subject and object, and for its emphasis on generalization" (Rosenau 1992:96). In effect, there can be no valid or reliable mapping of social action or relationships by observing or interviewing actors.

Rosenau (1992) concludes that, if these arguments prevail, sociology "is no longer an attempt to understand and bring objectivity to a topic; rather, it is a vivid narration of a novel variety, *if it is anything at all*" (emphasis provided) (40). "Sociology . . . would be merely (a) literary endeavor, more comfortable in the arts than the social sciences" (172). Jonathan Turner (1992) has predicted that "if the programs of the critics were followed, sociology would be a mixed bag of rather pedestrian philosophizing, historical and empirical description, ideological debate and commentary, vague scheme-building, commentary on current (and past) events, extreme relativism, and a general doubt that we can know or do anything" (167). If so, sociologists are to be literary critics.

There are two aspects to the postmodernist argument. The first is a general rejection of orderliness or standardization in research. Implicitly it says that "in research anything goes." The second is a strongly anti-objective, anti-quantitative, and anti-empiricist theme. It rejects the kind of research that is common in American sociology — that typically is referred to as positivistic.[13] I consider the two in that order.

With respect to the first theme, I also have criticized standardized practices in sociological research and the assumptions that underlie it (Smith 1991a). Sociologists engage in vehement quarrels over what methods should and should not be used, insist on the virtues of their favored methods, and ignore the ontological and epistemological implications. I suggest that these conflicts usually involve largely meaningless, false dichotomies (e.g., quantitative and qualitative [see Hammersley 1992:159-73; Wolfe 1992:778], survey and comparative-historical research, micro and macro) and lead to poor research. I note that the very people that ethnomethodologists refuse to classify and generalize about, classify and generalize with ease in their own lives. Politicization and ideological quarreling on these issues leads to doctrinaire approaches to inquiry (also see Layder 1990:177-82; Wagner 1992:217).

Reflexivity and historical specificity may limit the validity of sociological propositions, but they do not invalidate application of the standard scientific model to social phenomena. If that were the case, it also could not be applied to physical and biological phenomena, many of which also are transient, historically specific, and change as they are observed. Entities, processes, and rules that cannot be perceived directly are inferred or assumed. Scientific inquiry requires abstractions that inform observations, not phenomena that are frequent, permanent, or observed directly. The claim that objectivity is impossible because the attribution of meaning requires prior assumptions (see Wortman 1987:171) is convincing only because it is expressed in a novel way (e.g., Baudrillard 1988:167-72). All science requires assumptions to focus observations and make them data. Assumptions are not problems; being unaware of them and unaware that they negate certainty are problems. Sociologists, however, flay one another for making assumptions — as if they could be avoided. Stephen Turner observes (1992:126) that "much of what passes for metatheoretical criticism in sociology . . . appeals to standards of . . . adequacy that would, if . . . fully formulated, be easily seen to be utopian." Unwarranted demands for perfection afflict and hamper sociology.

Because a moratorium on criticism and a return to the established model of scientific inquiry seem unlikely, I reemphasize sharing one's work as a universal norm in scholarly research. The responsibility requires scholars to have reasons for every decision made in a study. Research is inquiry marked by dilemmas (e.g, what is the question, where to look for an answer, what to observe for data). Investigators must decide how to resolve them and, if the goal of research is to achieve results that can be shared, investigators must have reasons that can be shared for every decision made. They must be pragmatic in accepting the compromises and assumptions that these decisions and their implementation require. However, they cannot be arbitrary or frivolous. Because the validity of conclusions rests on the decisions that determine the body of evidence and the rules for interpreting and evaluating it, rather than routinely relying on one

research model or procedure, methods must be created or chosen for clear, explicit reasons in each study (see Wagner 1992:206-207). Because conditions and questions change and methods must be designed for each study, no two studies could be exactly alike. Strict replication, except by imagination, is impossible. These prescriptions do not imply that there is only one world to be known through scientific inquiry (see Bauman 1992:29-31). That is an issue for empirical research subject to the same standards.

Any similarity of this position to the skeptical postmodernist position that "as far as method is concerned, 'anything goes'" (Rosenau, citing Heller and Feyerabend, 1992:117, see 123), is illusory.[14] The skeptical postmodernist view on research follows from the denial of the legitimacy of communal and supracommunal standards, and, therefore, of any obligation to adhere to them (See Bauman 1992:35). To accept the need to make decisions on unique, unexpected problems in research, despite appearances to the contrary, is not to accept the view that in research anything goes. Rather, it is to argue for research driven by moral imperatives. Researchers are morally obliged not only to choose standards for making decisions, to gather needed data to make them, and to decide, but also to reveal each decision and the reasons for it. Moreover, the empirical character of things must be assumed. If it is, they may be objectified and, thus, treated as finite, ultimately perceivable, and subject to observation and classification. To say that inquiry is legitimated only by being done in a community that subscribes to norms that require sharing one's work with peers, submitting it to their scrutiny for evaluation, and taking their judgment of it into account does not mean that the views of the majority or of elite scholars should prevail. Rather, it means there should be discourse among equals. Without such discourse, some could become authorities whose views could constrain knowledge (see Addelson 1988:126-29 on how the failure to treat philosophers as peers contributes to their authority). The position is not congenial to postmodernists. Lyotard (1984) considers such legitimation to rest on the "principle of consensus" (60), which he rejects as legitimation by paralogy. In his language we disagree on whether metanarratives have lost their force as a legitimating device (see Bohman 1991:126-32).[15]

With respect to the second theme, a critique of positivism in sociology, I would like to make two points. The first is brief and concerns the ambiguity of the term *positivism*. Giddens (1974) began his book on the subject by noting that "the term . . . has been used so broadly and vaguely as a weapon of critical attack, both in philosophy and sociology, that it has lost any claim to an accepted and standard meaning" (2). Eleven years later, Bryant (1985) concluded his study by saying that "variations in the characterisations of positivism . . . are sufficiently diverse to prompt the question whether it would not be better to expel the term from the vocabulary of sociology and other social sciences altogether" (184). Other scholars have not judged the situation as negatively, but have noted the variety of usages.[16] The ambiguity makes it difficult to address the criticism directly because each aspect of the conventional usage of the term — what Bryant (1985) and Ross (1991:390-470) refer to as instrumental positivism in American sociology — requires a somewhat different response. General attacks on positivism are vague and difficult to address succinctly.

The second point addresses the nature of differences between postmodernist and positivist positions. My impression is that the philosophical premises that underlie the critique are not new and may have been expressed earlier. Postmodernism may only be their most recent manifestation. Indeed, Rosenau's comment (1992) that postmodernists "abandon any attempt to represent the object of study 'as it really is' independent of the process of inquiry" (97) is remarkably like that in the textbook (Ramsperger 1942) that Hempel assigned my class in the philosophy of science and that informed us that "the positivist . . . is committed to the view that he alone exists (112)" and, therefore, that one cannot assume that other things exist. Hence, one can have confidence only in one's experience and "it will be better to speak of science as a description of experience" (103). Moreover, because scientific statements pertain to observations of specific kinds of objects, Ramsperger also writes that "'object' is here to be understood in a broad sense . . . Anything whatever that may turn up for an observer is subject matter for factual propositions" (109).

Despite basic differences on other presuppositions,[17] as a prescription for inquiry, these aspects of the philosophical positivism that influenced sociology have basic parallels with the postmodernist argument.[18] For postmodernists, texts may be anything (and there is nothing more than texts, which themselves may be illusory to others); for positivists objects may be anything (though a presumed real but directly unknowable something underlies what is observed). Both consider the individual and the individual's experience as the points of greatest confidence (though for positivists one is obligated to make the effort to share *in the event that others should prove to be real*, whereas for postmodernists others are no more than incidental[19]); both assert that all that can be known are the operations that provide observations. Skeptical postmodernists' denial of the possibility of true knowledge (Baudrillard 1988; Lyotard 1984; Rosenau 1992) resonates with positivists' insistence on uncertainty and error, though extremely skeptical postmodernists even deny the possibility of any truth.

The implications of these similarities and differences are instructive for assessing postmodernism as a critique of research. (1) Despite uncertainty, positivists expect inquiry to lead to assertions regarding whether evidence disputes an understanding of *an* unknowable, assumed reality and to an account of how the evidence was produced, a process that any trained investigator can evaluate and reproduce.[20] Postmodernists expect inquiry to produce a fictionalized narrative that satisfies its producer and others need not understand. (2) Postmodernists expect (Lyotard 1984:4) data transformation to electronic form to facilitate an undesirable exteriorization of knowledge. Positivism emphasizes the need to account, to provide, and to give directions. It prescribes the exteriorization that postmodernists distrust so that others can scrutinize and use one's work.

(3) Positivism and postmodernism also differ with respect to willingness to accept the existence of others, confidence in language to screen and represent experience, and openness to the possibility of shared understanding. Positivists are more willing, more confident, and more open than postmodernists. Skeptical postmodernists are more pessimistic and disillusioned.[21] Thus, whereas positivists assert that perceptions and the reality of the world may differ and whether they do is unknowable, postmodernists believe that the very idea of a

distinction is illusory or a delusion. (4) In regard to the experienced world, both positivism and postmodernism are political positions that argue for active rejection of the status quo. Both advocates and critics of postmodernism agree that postmodernists disagree on whether it merits a radical or conservative response (see Smart 1992:176-79). In contrast, positivism — ever since Saint Simon's and Comte's versions — has been optimistic and ameliorative, assuming that knowledge and understanding lead to improvement.

These similarities and differences reflect differences in the underlying assumptions of positivism and postmodernism, assumptions about reality and the relation of language to it. They lead to very different views of what we can know and act on. D'Amico (1992:142-47), a philosopher, also has noted similarities between positivism and postmodernism by analyzing changes in Carnap's position to show that postmodernist assumptions about reality and the role of language can be much more congenial to empirical sociology. If so, it emphasizes the importance of weighing the accuracy of the empirical claims about current social conditions that underlie the postmodernist argument before accepting its claimed implications for sociology and sociological research.

Some Hypotheses as to Why Some Sociologists Accept the Critique

This contrast of positions on communication and research suggests that the conclusions that skeptical postmodernists draw for sociology do not necessarily follow from the premises. Rosenau, Bauman, Smart, Crook, and Gurnah and Scott have all examined the critique and rejected it in total or in part for various reasons. However, their discussions largely are accommodating or sympathetic and neglect its most telling flaw — inconsistency. If skeptical postmodernists insist that it is impossible to establish certainty or organize coherently, and that dissensus, noncohesion, and nonintegration in the social world are inescapable, then why write? Who could read and understand them? How would they know? What would it matter anyway? Merelman (1991) despite deep concern that the critique challenges the meaningfulness of his research on culture and politics, suggests that criticism in this vein is "cheap philosophical gimmickry" (232). Inconsistencies between postmodernists' arguments and behavior, however, should not be ignored. Calhoun, for example, does not, when he charges (1992:268) that postmodernist criticisms of social scientists' assumptions on the nature of the reality are not presented in an arguable and defensible form. Because even flawed critiques can have pervasive effects on everyday life and social science practice, we must ask why the critique, despite its many deficiencies, maintains its appeal.

Perhaps postmodernism is just another passing scholarly fad. Nonetheless, it is important to understand its significance for sociology. One way to do this is to ask why it commands concern when phenomenological and Marxist critiques have been accommodated, if not always embraced. The concern probably is a reaction to postmodernism's nihilistic strain and extreme ramifications, qualities that are likely to deter its accommodation. Sociology is a discipline with boundaries; both discipline and boundaries are anathema to and targets of postmodernists. Given this, why do some American sociologists

accept and others tolerate as serious analysis an assessment by literary critics who preempt their empirical domain to make assertions that would be rejected if they were presented as based on sociological data? The situation makes little apparent sense.

No single or definitive factor can explain this forbearance. Many may be at work alone or in combination. Regardless of the fate of the postmodern critique, three are chosen here for consideration as hypotheses because of their implications.[22]

1. Criticism of sociological research as positivistic is correct.

2. Postmodernism derives credence from its European origins.

3. Postmodernism is considered philosophical analysis and sociologists defer to it as philosophy.

These hypotheses may not be the most important possibilities, are intuitively based, and are not independent. Positivism is a philosophy; postmodernism and positivism share key premises and progenitors; some philosophers are postmodernists; and some scholars interested in the relationship of philosophy and sociology consider philosophy superordinate and sociology subordinate. In reviewing reasons for entertaining these hypotheses and in the ensuing discussion I sometimes omit "some" before "sociologists" and "philosophers." It should always be assumed.

POSITIVISM

Giddens' (1974) comments on positivism include the phrase, "the term has become one of opprobrium" (2). Holmwood and Stewart (1991) wrote "that social theorists present positivism as a *discredited* methodology" (13) (emphasis theirs). Benton found it strategic to devote the first four chapters of his study (1977) of the relationship of philosophy to sociology "to a critical discussion of positivism, both as a philosophical theory and in its effects on sociological theory" (12). Critical theorists consider positivism to be the major source of sociology's weakness (Adorno et al. 1969) and Alexander urges sociologists to move on to a postpositivist mode (1992). Papers by Seidman, D'Amico, Stephen Turner, Brown, Calhoun, Aronowitz, and Alexander, among others, in Seidman and Wagner's volume either directly criticize positivism in sociology or indicate that others have subjected it to fundamental criticisms.

Criticisms of positivism primarily focus on its ontological and epistemological bases[23] or, in the case of instrumental positivism, the lack thereof. The disrepute of positivism is so widely accepted that some critics distance empiricism from positivism (though American sociologists tend to equate the two). Regardless of these critical nuances, positivism is a discredited position that still attracts bashers, postmodernists included. It is plausible that sensitivity to the identification of sociology with discredited positivism may incline some sociologists to tolerate the postmodernist critique, even if they would not accept it in whole or in part.

EUROPEAN ORIGINS

The centering of the postmodern critique in Europe also may be a factor in its acceptance by many European and some American sociologists.[24] Although American scholars (e.g., Frederic Jameson, Stanley Fish) have led in urging its assessment and application (primarily in literary and cultural studies), and an American, Daniel Bell, popularized the idea that a *possible* quantum shift in social life might signify entry into a phase beyond the modern, postmodernism's intellectual roots are in European philosophy, particularly modern French philosophy. Its targets, empirical sociology and adherence to the standard model of science, are primarily American. Few of the movement's analysts that I cite are American. Very few of the social scientists Rosenau cites as having accepted the critique and transformed their work are American. Nonetheless, sociology's European roots may incline American sociologists schooled in that version of the discipline's origins and/or otherwise favorably disposed toward European scholarship to accept postmodernism as a serious, legitimate critique. At the least, it might foster openmindedness toward postmodernism on the part of some who otherwise would have little interest in or knowledge of it.

PHILOSOPHY

I hypothesize that some American sociologists (1) consider postmodernism to be philosophy and (2) consider philosophy to be superordinate to sociology, and, consequently, (3) treat the critique with forbearance. The conclusion is speculative. The hypothesis assumes an attitude (perhaps with roots in the role of philosophy of science in our training in methodology) toward philosophy rather than an informed response to philosophy. It does not require all sociologists to know or assess the work of any American or European philosopher, only that many have that attitude. There are obvious objections to the hypothesis. The relevant evidence is mixed, at best. I review several aspects of the argument.

Why might philosophy even be relevant? Deconstruction is not unique to philosophy; postmodernist depictions of contemporary life are not philosophy; and its major spokespersons are in the humanities. Given this, why consider the postmodernist critique philosophy? Primarily because disciplinary identities often are ambiguous.[25] The ambiguity applies to postmodernists. Some say postmodernists are Sophists and that Sophists are antiphilosophy (D'Amico 1992:142; Doubt 1993:285). If Foucault, Lyotard, and Baudrillard[26] are Sophists and Sophists are anti-philosophy, then leading postmodernists may not be philosophers.[27] However, because postmodernism's intellectual roots are in philosophy, it is not clear what to attribute to philosophy and what to attribute to its use for ulterior ends. Where does philosophy end and its application and reinterpretation begin? Regardless of whether leading postmodernists are philosophers, many of the analysts cited here do consider leading postmodernists to be philosophers and all attribute their premises to philosophers (e.g., Nietzsche, Heidegger, Wittgenstein, Gadamer, Derrida). It is plausible, then, that many uninterested and/or unconcerned sociologists could take the critique to be philosophy.

Why assume a real or perceived status difference between the disciplines? The evidence is circumstantial. Philosophy is older and more firmly ensconced in the academy than sociology. From some perspectives it is a parent. There is a status difference in the projects of the two disciplines. Philosophy's project is to produce superior knowledge.[28] In contrast, sociology's project is more mundane and its critical style and subject matter more humble. For one thing, the norm of value-free inquiry has been interpreted as proscribing evaluations other than those of the appropriateness, validity, and weight of empirical evidence (though sociologists have valued the rationalization of social life as a goal[29]). For another, everyday life provides much of sociology's subject matter, and common sense explanations and understandings compete with its abstract theories and concepts for acceptance.[30] They may even enjoy equal status so long as the difference is not ignored and they are not confused (see Crook 1991:194-96; Layder 1990:137-69). There also is a major contrast in the status of conclusions. Philosophy's proofs are universal and certain; sociology's conclusions are relative and probabilistic (see Kilminster 1989). These conditions can promote inequality; inequality can breed deference; and deference can foster a subservient attitude.

The process and its effects can be illustrated by one of several perspectives on the development of American sociology. According to this reconstruction, there have been at least three instances of intensified relations with philosophy whose cumulative impact remains. The first peaked before World War II, when philosophy was among several influences on the subject matter of sociology. Philosophers seeking an ideal social organization and process reasoned from postulates about social and political conditions based on casual observations, assumptions, and speculation. Their arguments employed selected examples and needed systematic empirical grounding. For sociologists who accepted this as their project, it delineated sociology's substantive domain.[31] In a sense, for them, sociology served philosophy. The pattern was reflected in training. For example, Lichtenberger's *Development of Social Theory* (1936), a typical theory text, begins with Plato and Aristotle, and continues on to later Greeks and Romans, Aquinas, Bodin, Hobbes, Locke, Rousseau, Vico, and Montesquieu, arriving at Comte several hundred pages later. Lichtenberger referred to their work as social philosophy. It was prescriptive — offering models of how society might be organized and how it might operate — or analytic — postulating rules that govern social relations or social organization.[32] Though no longer pivotal for sociology's substance, Rawls, Habermas, Taylor, and other philosophers still raise central issues for the agendas of sociological specialties (e.g., criminology, mass communication, political sociology).

The second centered on positivism[33] and spanned the mid-1920s to the mid-1950s.[34] Positivism promoted deductive over inductive theorizing and prescribed formalizing any discipline that was to be a science. It set standards for concepts, propositions, and research. An SSRC monograph series on methods and the *Unified Encyclopedia of the Sciences* typified efforts to make social inquiry scientific. Positivism's impact endures in the dominance of experimental and survey methods, statistical analysis, and research patterned in a theory-grounded, hypothesis-testing mode. As compared with sociology as "empirical philosophy," the disciplines were more autonomous, but standards still came

from philosophy to sociology. The third is the current involvement with postmodernism.

In each case, an autonomous philosophy has provided agendas, standards, and/or prescriptions for sociology.[35] In each, philosophy has had almost hegemonic status for sociology. Bourdieu's experience of a loss of professional status and self-esteem in switching from philosophy to sociology (Wacquant 1992:45) dramatizes how such inequality can he detrimental for any sociologist. In contrast to sociologists' sensitivity, many philosophers have been indifferent to, if not disdainful of, sociology.[36]

Social philosophy's role may have waned,[37] but philosophy's superordinate status was and is manifested in various ways.[38] Durkheim (1933:370-71) designated philosophy as collective conscience to the sciences even though he deplored its abstractions (Ragin and Zaret 1983:732). Adorno (cited by Crook 1991), with experience in both disciplines, wrote that philosophy "take(s) its specific scientific material preponderantly from sociology . . . (because) . . . the idea of science is research . . . that of philosophy is interpretation" (102). Interpretation is the source of meaning and significance. Merleau-Ponty ([1960] 1974:95), although urging an end to the segregation of the two disciplines, advised sociology to look to philosophy for understanding (107). Kilminster (1989) charges that philosophy is losing its role, and, to save itself, imposes a hierarchical division of labor on the social sciences. All the above points lend plausibility to the hypothesis that some sociologists might consider the critique philosophy, might consider philosophy superior, and, thus, might tolerate, if not accept, the critique.

How May the Situation Make a Difference to Sociology?

The factors specified in the hypotheses — sensitivity to being considered positivists, acceptance of fundamentally flawed arguments if they have European origins, and deference to philosophy — all portray sociology as a subordinate, weak discipline. Because subordination and weakness are pernicious, I consider their implications for the discipline and its future.

There are two related implications of an inequality between philosophy and sociology for sociologists' forbearance toward the critique and its impact on the discipline. (1) It inclines sociologists to accept passively and not scrutinize critical philosophical analyses. (2) Therefore, most sociologists who consider postmodernism to be philosophy tolerate it. The first could be a by-product of longstanding patterned relationships that plant the seeds of inequality.[39] Philosophers propound standards and rules for the structure of theory, the relation of theory and research, and the conduct of empirical inquiry that sociologists accept. Philosophers' critiques of sociology can be uninhibited and invidious (see Bohman for an exception); sociologists accept them. Few reciprocate.[40] In essence, philosophers' role is to decree and criticize, sociologists' role is to accept. The relationship may explain why there is no sociology of philosophy.[41] A sociology of philosophy would reveal that philosophers' work is no purer than sociologists' and that philosophers also do empirical

research[42] that, by the standards of evaluation for empirical research, is no better than sociologists'.

The practice of philosophy goes unexamined. The discipline's "ivory tower" reputation — socially and historically unsituated, pursued in isolation from the real world — diverts scrutiny. A sociology of philosophy would examine social influences on philosophers' work, as Gouldner did in *Enter Plato* (1966), or provide socially situated interpretations of that work, like those of Zeitlin (1968) and Coser (1977). It would show that philosophers, like other scholars, respond to and try to influence their social, economic, and political environments.[43] The ivory tower myth shields philosophy from the sociology of knowledge and discourages a sociology of philosophy. This helps sustain the inequality.

Ontology and epistemology draw attention to the assumptions and the irreducible uncertainty in empirical research.[44] They become ammunition that sociologists use to castigate one another for striving to be scientific. Sociologists' critiques of research practice tend to be more extreme for sociology than for other disciplines. Morbid, destructive self-criticism on the basis of utopian philosophical standards pervades the discipline.[45] Charges of scientism grow in force and volume with the continued discrediting of positivism (see Peters and Rothenbuhler 1989). Studies of scientists' actual work patterns are cited to legitimate alternative approaches (see studies cited in note 6). Sociologists become chronically uneasy with reminders that they never can be sure that anything they presume to know outside themselves exists. Concern that disciplinary concepts lack meaning or currency in everyday life fuels nagging doubts that their referents exist. These debilitating insecurities are magnified by the postmodernist charge that the inability to verify meanings vitiates their work. In this way, the confluence of a sense of inferiority to philosophy, the equating of postmodernism and philosophy, and insecurity in the face of elegant European theorizing and criticism not only encourages tolerance of the critique but also undermines confidence in sociology.

Postmodernists' claims that sociology is a political project also disturb and divert sociologists even though postmodernism, too, is a political project (as well as an application of philosophy). They lose sight of the fact that the charge of being political is a truism that applies to and does not invalidate any discipline. Every field of knowledge, including philosophy, influences and is influenced by its circumstances. Sophisticated scholars know this. Even if such concepts as society and culture were invented to serve powerful social and political interests,[46] their survival rests on how well they predict and explain and on their relation to other explanatory systems, not on their origins.

The crux of the matter is that postmodernist contentions about whether there should or can be social sciences as now practiced rest on empirical claims and interpretations of their meaning. The qualitative shift that postmodernists claim has occurred in people's relation to events and to one another is empirical and rests on anecdotal rather than systematic evidence. Its meaning is postulated. Baudrillard's exposition (1988:141-48) of a transformation of the real to fantasy and the hyperreal is brilliant polemic. The conception of a postmodern world need not be wrong because it is based on selected examples for data and on *ad hoc* interpretations for meaning, but it must be tested with systematic data and other frameworks for interpretation. No matter how insightful, a critique

built on empirical claims is subject to evaluation on the basis of systematic empirical data. Entertaining an assessment from an intellectual conceit that passes as philosophy and is particularly inimical to sociology (Smart 1992:180-81) perpetuates sociology's inferior status and weakness. It also is an unwitting surrender of turf.

The aggressive colonizing of the sociologies of mass media and culture by postmodernist cultural and literary scholars is only the latest incursion invited by sociology's institutional vulnerability.[47] The sociologies of organization, crime, family, politics, and public opinion already have been or are being appropriated (see Smith 1991a:2). There may be several reasons for this situation.

1. It may be inevitable for a discipline dominated by positivism; overconcern with methods can lead to neglect of substance.[48]

2. It may be an indirect result of the view that sociology is overarching and generalizing and, therefore, has expertise over all social reality. If so, sociologists are victims of their own smug complacency.

3. Sociology may have grown too big, and, because there is more knowledge than can be digested, it has fragmented in substance and purpose. This facilitates raids because most sociologists know little and care less about what is happening in distant specialties (Collins 1992:187-88).

Regardless of the reason, when resources are scarce, being correct about the social science hierarchy or the proper way to do sociology is irrelevant. Scholars who worry that their discipline may have nothing new to say but still must compete for students and tight budgets, seek and pursue any opportunity aggressively. All of sociology is appealing turf to invade.[49] For a discipline whose institutional support is primarily academic, loss of turf portends a bleak future.

Conclusion

Even if postmodernist premises are suspect, the possible prevalence of the conditions that the analysis presumes cannot be ignored. People increasingly may be divorced from reality, assimilation may not reduce heterogeneity, diversity may be increasing, integration may be an unattainable goal, and change and dissensus may describe social reality better than stability and consensus. If so, these social conditions will influence sociological theories, models, and concepts (see *Sociological Theory* 1991, 1992). Giddens's concept of structuration, Bourdieu's method of epistemic reflexivity, and Touraine's vision of society as social movements exemplify the possibilities. Computers can expedite these developments.[50] Research also will change. Methods increasingly will be shaped and judged in terms of their intrinsic relation to subject rather than their conformity to abstract method-sets (e.g., survey, experimental, comparative-historical method). The reasons for choices rather than specific methods and techniques will be taught; data gathering will be conceptualized as social behavior rather than as inflexible rules of action.

Even if the dire implications of the postmodern critique for sociology are neither logically nor empirically necessary, we may not be assured of escaping its influence. Jonathan Turner (1992), after assessing the critique, concluded that:

> with the invasion of so many new intellectual stances from Europe, as well as the fostering of those initiated in the United States, theoretical activity is partitioned into too many "camps," "orientations," "perspectives," or "paradigms" for any general theory, cutting across this diversity, to ever be possible. Such is especially likely to be the case in a field that will not even take itself seriously as a science, preferring instead to be a mixture of history, philosophy, social commentary, ideological advocacy, and empirical description. (175-77)

Collins (1992:187-88), emphasizing fragmentation, also is pessimistic. I have argued that the discipline stagnates while sociologists fight over ontological and epistemological matters (also see Wagner 1992:217).[51] It is a mistake to focus only on postmodernist criticism when dissension is rife.

The postmodernist influence on sociology could lose force more quickly than positivism did. However, that is secondary. Defusing the critique will not make sociologists less prone to accept unwarranted criticism. In concluding their analysis, Gurnah and Scott (1992) write that "the entire modernity versus postmodernity debate has done little to change the relationship between sociology and philosophy. The old subordination remains" (161). Though neither this analysis nor theirs might have been necessary if the disciplinary relationship had been more equal, they are forceful reminders to sociologists to accept the dynamism and complexity of their subject — and think for themselves.

Notes

1. Nonetheless, it was the topic of a symposium in *Sociological Theory* (1991) to which Seidman, Alexander, Antonio, Lemert, and Richardson contributed. Several other articles on the subject also have appeared in that journal. Both Aronowitz (1988) and Gitlin (1989) have written on postmodernism and politics. Seidman and Wagner's edited volume (1992) includes papers by three of the above authors as well as six other sociologists. When people as respected as Collins, Gitlin, Calhoun, and Alexander address the critique, it seems reasonable to treat it seriously even if it is not widely accepted.

2. See Lemert's (1992) impassioned plea for a sociology that does not employ universal categories because that would imply a realist epistemology when, in fact, real people "make very general statements . . ." despite "the fact that they do not and cannot believe in a world that is whole or real outside of what they experience and express" (40-41).

3. An issue of *Theory, Culture and Society* devoted to postmodernism is replete with discussions of these differences (see Bauman 1988:217; Featherstone 1988:197; Kellner 1988:241). Bernstein (1992) says of the situation that "the terms 'modern' and 'postmodern' are not only vague, ambiguous, and slippery, they have been used in conflicting and even contradictory ways" (200). See Smart (1993:11-39) for a full discussion of the many usages of the term.

4. Baudrillard (1988:57-97) considers the alienation and fractionation of value and its divorce from that which is valued under capitalism as crucial. Lyotard (1984) identifies technological innovations that alter and depersonalize that which is valued as being among the crucial factors expediting the transformation. Both claim that computing has enhanced the commodification of knowledge and that the broad influence of that process is a major feature of the postmodern world.

5. Rosenau distinguishes skeptical and affirmative postmodernists and moderates and extremes of both types, and notes that the high correlation between (1) complete rejection of or revision of modernism and (2) extreme or temperate expression makes for very varied characterizations of postmodernist commentary (8, fn. 11). Smart (1992:167), for example, prefers to distinguish European and American types. Because their position is the most extreme and carries the most drastic implications for sociology, I focus on versions that Rosenau calls skeptical.

6. The critique's relevance to sociology may reflect its Nietzschean roots. Lepenies (1988) refers to Nietzsche as "the anti-sociologist. . . ," (41) who "saw in Comte . . . a continuation of . . . eighteenth century . . . 'sensualism in epistemology'" (40-41). Its acceptance by sociologists as a legitimate critique may have been expedited by its use of deconstruction. Deconstruction complements the social constructionism that appeals to many sociologists. It also is employed by Marxism and feminism, both of which argue that conventional sociological depictions of society are constructions that serve the interests of elite white males. Accommodation to these critiques may have facilitated postmodernism's acceptance (see Nicholson 1992; Richardson 1993).

Relativism, an influence on sociology even earlier than Marxist and feminist criticism, also may contribute to some sociologists' forbearance with postmodernist claims. Relativism, when applied to the sociology of knowledge, has contributed to what has come to be known as the sociology of scientific knowledge, which treats the dominant conventional representation of scientific practice as a fictive construction that does not represent actual scientific practice (see, e.g., Barnes 1975:ch. 5; 1982:ch. 2; 1985; Lynch 1985; Latour & Woolgar 1979). The more general concern with the discontinuity between the actual and claimed practices on which assertions are based also was a factor in the earlier development of ethnomethodology (see Barnes 1982:94-101; Lynch 1985:6-10; S. Turner 1994:38-43). Practitioners of a discipline that argues that social factors shape and impinge on behavior, beliefs, and values are, perhaps, more open than practitioners of other disciplines to entertain the possible merits of, if not accept, the postmodernist critique. See Stephen Turner 1994 for an explication and discussion of the deeper roots of these connections.

7. Cf. fn. 26. Charles Lemert, in a summary of the postmodernist argument consistent with all the versions and aspects I have examined, states (1992:23-24) its principles as follows:

1. Reality is discussable — not much more than this.
2. Language is primary.
3. Reality is figurative, available only in language.
4. In language one can say any and everything, including the most general of things.
5. One can never escape one's language, including all other general statements about things.
6. All the above is a historical event more than an ideological position or a logical argument.
7. Hence, postmodernism is both the end of modernity and dependent upon modernity for its language.

8. Rosenau (1992:95) and Bauman (1992:33) cite Baudrillard as claiming this.

9. Rosenau (1992) says "The skeptics are dubious about the possibility of communicating altogether" (18).

10. Bauman (1992:54) refers to socialization and culture (including language) as derandomizing the voluntary actions of free agents.

11. Baudrillard (1988) would reject this definition. Though we agree that the media entail a one way use of power to influence and, therefore, are not engaged in communication, he says that communication may have utility only "if one defines it as *anything other* (emphasis mine) than the simple emission/reception of information" (207). This is the antithesis of our definition.

12. Zaret reports (1980:85; 1985:19-40, 53-60) that as early as the late 16th century, the nascent English popular religious press was important in forming the religious concepts of Puritan laymen by mediating their relations with clergymen.

13. Using Rosenau's (1992) index, I easily found at least a half-dozen references to positivistic social science as a specific target of postmodernist criticism.

14. Gellner's (1992) understanding of Feyerabend is more nuanced and sympathetic. "It isn't so much that 'anything goes,' as that it becomes difficult to explain why this should *not* be so" (110-11). Feyerabend was a student of Popper. This makes credible D'Amico's (1992:145)

surmise that Feyerabend's methodological anarchism actually derives from Carnap. If so, Lyotard (1984:76) may not use the phrase as Heller and Feyerabend do when he refers to postmodern cultural practices as being guided by the idea that "anything goes." See Morris' (1992:259) criticism of David Harvey for misunderstanding Lyotard's usage.

15. If affirmative postmodernism prescribes "feelings, personal experience, empathy, emotion, intuition, subjective judgment, imagination, as well as diverse forms of creativity and play . . . as alternatives to scientific method" and leaves the "content of these terms and their methodological significance . . . relatively vague and difficult to communicate to others" (Rosenau 1992:117), then it also differs from the accountability prescribed by radical social theory (see Crook 1991:200-14). That is a responsibility to be aware of and reveal one's interests and values and how they may affect decisions on topics for inquiry, observations, and conclusions. Although not always honored (see Crook 1991:201), conventional scientific norms also permit accountability. Skeptics deny there are alternatives.

16. Cf. Benton 1977; Brown 1990; Holmwood & Stewart 1991:11-25. Bryant (1985:2) credits Percy Cohen with a more systematic analysis of its meaning. Most critics, including postmodernists, use positivist as an epithet to refer to empiricism, quantification, the use of statistical models, formalism, and overconcern with procedures, singly or in combination. Because they identify these features of social science with survey research and statistical analysis, "positivist" often is used to describe the latter. All these referents are subsumed by instrumental positivism (Bryant 1985:133-73).

17. The meaning of similarities in the face of different underlying assumptions is debatable. However, postmodernists' efforts to address a public indicate that, regardless of rhetoric, they seek understanding and support from others. If so, how they arrive at empirical assertions becomes crucial and both parallels and differences in positions may be significant.

18. Wittgenstein has been identified as a progenitor of both. He sympathized with the program of the Vienna Circle (Bryant 1985:110) and is cited by postmodernists as a source for their arguments.

19. This may reflect the contrast between the postmodernist position that we cannot overcome the uncertainty and unreliability of *any* attempt to communicate and the positivist belief that they can be overcome by clarity, precision, and order. These positions reflect a deeper division on materialism.

20. Ramsperger writes that "Science is at least an orderly account of experiences; this implies that it must select and classify experiences in such a way as to *give* them order (103) . . . The purpose of science . . . is to facilitate the prediction and control of experience by providing propositions and formulae which express, in the most economical manner, the relationships between observable objects and events (106). . . . The cognitive meaning of a statement consists, then, in the directions it gives for getting perceptions of a definite sort (107) . . . No statement about existence is meaningful unless it contains, at least implicitly, directions for the observation of a specific kind of object" (109).

21. Calhoun (1992:265) has described many as happy relativists who eschew the gloom it can bring. However, pessimism may be too mild a term for Baudrillard (1988), who has written that "Nothing can insure us against fatality, much less provide us with a strategy" (203).

22. Those aspects of the sociological tradition that have encouraged the constructionist view of knowledge and current developments in the sociology of scientific knowledge in particular (see note 6) are not discussed here. They function more to provide a general climate in which the factors selected for discussion may take on increased relevance.

23. On these grounds, Brown (1990:322) has described positivistic absolutism as self-refuting.

24. The conjunction of European criticism and American empirical social science may be more than coincidental. The two long have been in a state of tension arising from matters that have little to do with issues of validity. The feelings of at least some American scholars are exemplified by Stinchcombe's accusation (1993) that British sociologists are parochial, and by Jonathan Turner's (1992:156) claim that it is unfashionable to identify as a positivist because American theory circles are inundated with European sophistication in the form of phenomenology, hermeneutics, structuralism, and critical theory. The tension on the European side may reflect concern about inferior intellectual resources, influence, and power that have resulted in

the shift around 1930 of major advances in social science from European to American sources (Deutsch, Markovits & Platt 1986).

25. Addelson (1989) refers to Peter Winch as a philosopher who already has understood and implemented, even if insufficiently, her call for philosophers to become sociologists. She says of her own semiconversion that "I was trained as an analytic philosopher, and I started to become a sociologist in 1974" (140). Gellner (1973) ascribes to Winch the view that "philosophy and sociology (in a broad sense) are very similar, if not almost identical" (48) and, given Winch's reasons for that view, that "the implicit corollar(y) . . . is . . . that philosophy really is applied sociology." Gellner himself has held academic appointments in philosophy, anthropology, and sociology. Others (e.g., Schutz, Foucault, Habermas) have had similarly fluid careers. Several sociologists (Giddens 1984:xvii; Lemert 1992:18-19; Doubt 1993:285) say that social theory inevitably involves analyses that spill over into philosophy and that much sociological theorizing becomes indistinguishable from philosophizing.

26. Nonetheless, Bogard (1990:1), for one, refers to Baudrillard as a social philosopher.

27. Calhoun (1992:265-76), Stephen Turner (1992:102), and others, identify the rejection of philosophical foundationalism and the depiction of most sociological theories as foundational to be essential characteristics of postmodernism. D'Amico (1992:142) likens most philosophy to foundationalism. Postmodernists reject foundationalism because foundational claims are political commitments to idealistic positions. Assertions as to the acceptability and priority of foundational claims, in turn, are only exercises of power. Calhoun maintains that alternatives to foundationalism just don't appear. In any case, in this light the postmodernist position is antiphilosophy as well as antisociology.

28. Bauman (1992:115) interprets the *modern* and *postmodern* modes in sociology and philosophy as legislative and interpretive. He cites Plato (quoting Socrates), Kant, and Descartes to support the argument that philosophers see their role as pursuing inquiries that rise above everyday life so as to derive *superior* knowledge that can be used to legislate in the interests of the people (116-17). Ruth Macklin (1985:276), a philosopher, classifies philosophical writings as being of five types, at least the first three of which — defining terms and analyzing concepts; attending to the logic of arguments, detecting fallacies, and uncovering assumptions; and analyzing and interpreting writings from both within and without philosophy — imply that philosophy has methods and capabilities that justify analyzing, criticizing, and prescribing for other disciplines.

29. The development of sociology can be construed as one effort to achieve the Enlightenment's goal of facilitating a more rational social life (see Smart's discussion of Habermas's view of modernity, 1992:162). Bauman (1992:39) describes Giddens' assessment of sociology as being constituted by the "rational analysis of society (which itself is) . . . subject to the processes of continuing rationalization." The same aspiration is expressed in James Coleman's recent (1993) presidential address to the American Sociological Association. Rickman (1983), a philosopher, insists that "any systematic study of society should be grounded by reason . . . [and] philosophically treated" (3).

30. Bauman (1992) says sociology has inherited philosophy's project of producing superior knowledge on which to base legislation of a better life. It has pursued the project by "the critique of common sense" and by proposing ways to avoid social "dis-order." Eventually, this has "led inexorably to the denial of the human capacity for generating adequate self-knowledge" (121-22). He claims that this was both Durkheim's and Weber's intention and is reflected in their explanations for their methodologies. He asserts that for orthodox sociology "lay knowledge of society members cannot be trusted as representation of truth. To put it bluntly, people on the whole do not know what they are doing or why they are doing it" (124). Earlier, Simmel had noted the co-existence and irreducibility of the syntheses of social actors and of analysts. Neither is privileged because each is conditioned by the interests of the person in the role (see Crook 1991:193). The distinction between actors' and analysts' perspectives is crucial in ethnomethodology and phenomenological sociology. Compare also Misgeld's analysis (1986:83-84) of why natural language and "common sense reasoning could not be trusted to give (sociology) a correct view of society" (84).

31. Addelson (1992:141, fn. 4), for example, writes with respect to sociological symbolic interactionism that it has "philosophical roots in American pragmatism of the early twentieth century . . . We must follow the pragmatist philosophical position forward to one of its natural outcomes in a sociological tradition of today . . . Becoming a sociologist requires working

within a research tradition that has corrected and extended the original, philosophical ideas of its founders by making them empirical."

32. The philosopher William Montague (1927) elaborated the concept of social philosophy. If philosophy is "the attempt to give answers to the kinds of questions that have not yet been answered with definiteness and certainty by science," social philosophy attempts to answer two main questions: what is society, and what goal or end should be used to evaluate social practices. As for the relationship, "philosophers are the advance guard for the army of scientists. They spy out the new land as a necessary preliminary to its successful occupation" (466).

33. Positivism reflects the analytic-synthetic distinction of the Enlightenment and is manifested in logic, formal languages, and meta-mathematics. It is applied to science as conceptual and linguistic analysis. See Addelson (1992:123).

34. Throughout this article I conflate European logical positivism in philosophy and American instrumental positivism in sociology. The first is a response to a variety of traditional problems in European philosophy (Bryant 1985:109-11). The second (Bryant 1985; Ross 1991:390-470), a somewhat earlier self-generated position, has roots in an optimistic commitment to what Ross calls scientism as a means to social betterment. It may have derived from John Dewey and his school of philosophy. The confusion may owe to the fact that many European positivists had come to the United States during the 1930s and held university appointments in the same institutions as sociologists who were instrumental positivists. When I was an undergraduate in sociology in the early 1940s, the two were not being clearly distinguished and logical positivism was being cited as a justification for research practice.

35. The pattern also has been noted by Bauman and by C.G.A. Bryant. Bauman (1992) writes that "the declaration of intent associated with philosophy impelled and agitated by legislative reason was, overtly or implicitly, an anti-sociological manifesto . . . Philosophy . . . left sociology a choice between the role of handmaiden . . . or facing the prospect of dishonourable discharge without references" (143). Bauman goes on to say that interpretive philosophers have drastically changed this situation, but expresses it as their decision. This still implies hierarchical relations. Given the pervasive long-term influence of established institutions, the idea that hierarchy is easily changed on the basis of purely intellectual decisions is questionable. Bryant (1992) writes that "the relationship between sociology and philosophy has long been contested by sociologists and philosophers . . . [S]ociology can do without philosophers but not without philosophy. Sociology inescapably raises issues of ontology, epistemology, and normative theory. Either sociologists must rely implicitly or explicitly on positions articulated by philosophers, or they must engage the issues themselves and come up with something better" (137). His discussion is based on what he describes as Kilminster's brilliant analysis of how philosophers have used their greater status to impose their definition of the relationship.

There are, of course, exceptions. Empiricists like William F. Ogburn ignored philosophy. Many historical sociologists, who would disidentify with Ogburn, also emphasize detail and particularity in their work and ignore or contest the relevance of philosophy for sociology (see Skocpol 1987).

36. Cf. Gellner's (1973) statement that the philosopher Peter Winch:

> checks his conclusions by arguments . . . with the general methodological and programmatic views of major figures in the thought *about* the social sciences. But the social sciences are also a *reality*, and one which, however imperfect, did not wait for recent philosophic revelations for permission to actualize itself. To this reality Mr. Winch in his rather Platonic procedure does not pay much attention. Had he done so, he . . . would at the very least have avoided the somewhat awe-inspiring posture of a philosophic Superman flying in from outside and setting things right for the earthbound social scientists. (47-48)

Addelson, D'Amico, Bohman, and Merleau-Ponty, in contrast, respect sociology and consider it in some respects an equal or even a leader in a common enterprise.

37. Amitai Etzioni, Philip Selznick, Herbert Gans, Jeffrey Goldfarb, and Robert Bellah are all American sociologists who argue for sociological analysis that is normative and can play a policy role. They might be called social philosophers. The nature of social philosophy is captured by Lemert's (1992:33-34) distinction between (epistemologically grounded) sociological theory and (politically grounded) social theory. It is a permeable distinction that reflects the

ambiguity of the line between philosophy and sociology. If Selznick's work on community (1992) had been done as a service to Taylor's analyses of modern life (1989, 1990, 1991), it would provide an example of contemporary social philosophy.

38. Lyotard (1984) makes this point more subtly. "To the extent that science . . . seeks the truth, it is obliged to legitimate the rules of its own game. It then produces a discourse of legitimation with respect to its own status, a discourse called philosophy" (xxiii).

39. A sociological inferiority complex toward philosophy might have roots in sociology's failure to become established in European institutions at the height of its classical period in the early 1900s (Wagner 1990). Wagner cites Croce's 1906 description of sociology "'as a barbaric positivistic incursion into the domain of philosophy and history'" (225), and asserts that, as a newcomer, sociology would not be welcomed by such established disciplines as philosophy and that "early sociologists were aware of this institutional problematique" (232-33). Some philosophers acknowledge that there is an unbalanced relationship between philosophy and the social sciences and propose restructuring it as a relation between partners (see Bohman 1991:235).

40. Gurnah and Scott (1992) provide a rare exception in saying that "the continued interlacing of philosophy and sociology distorts sociology and limits its critical impact . . . The tension between sociology as an empirical investigation of the culturally and historically specific and philosophy as a reflection of the constant and universal has haunted sociology from the start . . . Our thesis is anti-philosophical . . . [S]ocial research is limited if it is structured by philosophical concerns" (1). Our reasons for judging the relationship negatively differ, however. Gurnah and Scott want to maximize sociology's critical force and see any association with or grounding in positivism as foundationalism, which, they argue, makes sociology vulnerable to flaws that come from an association with philosophy. I (1991a) argue, in contrast, that a sociology influenced by positivism also is critical. Postmodernists (or others loath to assume an empirical reality) differ from both positivists and critical theorists, claiming that any or no assumption about reality may be made and, in any case, that it does not matter.

41. Bauman's (1992) discussion of the relation of sociology to philosophy refers to social philosophy but not to a sociology of philosophy.

42. Before philosophy and psychology split over empirical research, G.H. Mead grounded his graduate work in philosophy in empirical studies of the mind. Later, members of the Frankfurt School did empirical studies (cf. Aronowitz 1992:291-94) of the media (Adorno, Lowenthal) and prejudice (Adorno, Horkheimer); Kaplan, Rudner, and others did content analyses (applied hermeneutics) and experiments (applied philosophy of science and knowledge).

43. Shalin (1992:239-44) shows how an interest in diagnosing and controlling political developments shaped the work of continental philosophers from the French Revolution to the rise of the Nazis.

44. Jonathan Turner (1992:156-57) attributes problems in sociological theorizing to the detrimental effects of philosophy on the work of sociologists. Stephen Turner (1992) places its source in the rigid application to sociological research and theorizing of absolute standards that derive from philosophy.

45. Compare Stephen Turner's comment quoted in this article in the methodology section.

46. For example, see Smith (1991b) on the promotion of a national culture by political and cultural elites as a project to consolidate power.

47. Peter Wagner's analysis of sociology's failure to become established in European scholarly institutions employs the argument that disciplines legitimized themselves by claiming a sphere of interest not already claimed by an established discipline. Post-World War I German sociology was an exception. Von Wiese succeeded by arguing "for a reductionist conception of sociology that would avoid all possible conflicts with other disciplines" (236). Wagner notes that only in the United States, where disciplinary boundary setting and professionalization were even more extreme, did that concept play a similar role in establishing sociology institutionally. Subsequent developments varied by country, so each must be understood in terms of its own conditions — structure of the university system, role of the state, etc.

48. However, Kaplan (1964) espouses the view that attention to methods requires attention to substance.

49. David Zaret has observed that *tour de force* literary critiques based on textual analysis are a low cost tactic for invading turf (Personal correspondence).

50. Postmodernists decry what they believe to be the impact of computers on knowledge and thought. It is intriguing to speculate on what postmodernism would be like if analog rather than digital computers had dominated.

51. Two critics of conventional empirical research (Bryant 1992a, 1992b; Fuller 1992,1993) are currently embroiled in a bitter debate in which each claims that his version of reflexive sociology is the only appropriate model for sociological inquiry. Ironically, to support his case, each cites Duncan, Blalock, and Lieberson, all of whom urge care and creativity in reasoned methodological critiques of specific weaknesses in quantitative research practice.

Perverse Effects of Social Support: Publics and Performance in Major League Sports*

ERIC M. LEIFER, *Curriculum Products, Inc.*

Abstract

Random samples have been used to link social support to a diversity of positive outcomes. When viewed within an interaction system, however, social support appears within a context of contention and disserves some while serving others. The manner in which social support is generated can both induce and suppress outcome inequalities. This is shown in the effects of fan support on team performance in major league sports. For the sports most dependent on partisan local publics, fan support functions to suppress the performance inequalities that leagues build into competition. For the sports that have cultivated expectation-driven national publics, fan support functions to induce performance inequalities that leagues seek to eliminate from competition. A computer simulation reveals that the entire amount of actual performance inequality in national public-oriented NFL football can be explained by this perverse effect of supportive publics. Perverse effects, it is argued, are essential to the functioning of interaction systems.

Social support has been linked to a diverse array of positive outcomes, including stress reduction (Haines & Hurlbert 1992; House, Umberson & Landis 1988), decreased mortality and suicide (Cornell 1992; Pescosolido 1990), career mobility (Ibarra 1992), church membership (Bainbridge 1990), and life satisfaction (Stevens 1992). Random samples of individuals have provided the empirical bases for these links, using measurement instruments that transform social support into an individual attribute. When social support is examined within the contexts where it operates, however, its role as a panacea ceases to be so clear. Social support is mobilized when there is contention between individuals and groups and is proffered only at the risk of taking sides. The support one side receives can easily be construed as a lack of support by another. Far from

simply making everything better, social support can function to induce, reinforce, or sometimes diminish various inequalities, and which effects it has depends on where and how it gets cast (Chase 1984; Dekeseredy 1990). Its distributional, as opposed to therapeutic, consequences need to be explored.

Social support gets cast on multiple bases, and as a result has multiple consequences. It may flow from deeply ingrained particularisms, or partisanships, like loyalty to family or tribe or city (White & Riedman 1992). Or it may derive from more universalistic sources, like talent or past performance (Hougland, Billings & Wood 1990). The mix of these bases can be complex. In Whyte's (1946) classic study of the Norton street gang, loyalty to the gang ensured each member some security and stature in the neighborhood. Yet intense focus both within and across rival gangs on performance in a stream of activities, like fighting, baseball, dating, and bowling, served to link support also with performance. In major league sports, the setting used in this article, the partisan support that local publics give a home team has been linked to a widely recognized home advantage factor, which can increase the home team's chances of winning by as much as 30% (Mizruchi 1985; Schwartz & Barsky 1977). Little attention, however, has been given to the different kind of support that came with the mobilization of national publics through televised sports. Instead of loyally following teams as fans, modern sports enthusiasts are drawn into leaguewide competition in the search for winners to support. Partisanship is replaced by expectations regarding performance in determining how support is allocated. This article shows that these different bases for support can have different consequences for the way support affects performance outcomes.

Using game-outcome data, an attempt is made to disentangle the distinct effects of partisan local publics and expectation-driven national publics on performance across the four major league sports. A computer simulation is then used to explore the cumulative consequences of partisan and expectation effects on season performance inequality, to see how much actual performance inequality can be accounted for solely by the social support of publics. The exercise reveals two perverse effects of social support. Where major leagues pursue competitive balance, national publics emerge that can actually sustain performance inequality (Leifer 1990a). Where major leagues seek to reinforce the dominance of large-city teams, the partisan support of local publics promotes performance leveling. In the conclusion, we conjecture that perverse effects of social support may be a general feature of sustainable social systems.

Background and Hypotheses

There is long-standing evidence that supportive publics can favorably affect a diverse array of performances (Allport 1920; Cottrell 1972; Paulus & Cornelius 1974; Travis 1925; Zajonc 1966). In major league sports, teams play half their games in the same "home" location and have long depended on the partisan support of home crowds for both their financial and their competitive performance. In accounting for game outcomes, the *Chicago Tribune* made more references to home and away location than to such factors as talent, injuries, and momentum (Edwards 1979). The actual magnitude of the home advantage

(home win proportion - away win proportion) has been calculated for a diversity of sports settings. Using a composite of prior studies, Courneya and Carron (1992) calculated the home win percentage (HWP) and home advantage (HA) for the four sports (using college and professional versions), which correspond closely to the major league data used in this study, as seen in Table 1. While the home advantage is an accepted fact, its causes and consequences remain somewhat mysterious. We will argue that it derives from a "partisan effect" of supportive local publics.

As Schwartz and Barsky (1977) originally observed, the home advantage is strongest in the indoor sports of hockey and basketball, where partisan home team support can be most intense. In the two predominantly outdoor sports, the stronger home advantage of football seems consistent with its larger and more enveloping crowds. When professional football teams (1960-90) have domed stadiums, the home advantage is .147 compared to .121 for teams with open stadiums. For Major League Baseball, Zeller and Jurkovac (1988) found a home advantage of .105 for teams with domed stadiums compared to .072 for teams with open stadiums, though I found only .089 versus .077 using a longer time frame (from the first domed stadium in 1965 to 1990). To further pursue the apparent importance of crowd intensity, actual crowd size and behavior must be examined.[1]

Within-sport efforts to confirm the role of crowd density have, however, failed to produce clear results across studies (Dowie 1982; Pollard 1986). Density, alone, is not sufficient to boost performance. For example, Thirer and Rampey (1979) studied the effects of spectator behavior on performance in college basketball games and found that antisocial behavior, such as shouting obscenities and throwing objects on the court, negatively affected the home team more than the visiting team by inciting "dysfunctional aggression" by home players. Greer (1983) focused on sustained, but not antisocial, protest among spectators, analyzing the effect of such instances on a number of performance measures. He found that episodes of spectator protest were related to an increase in the performance advantages enjoyed by home teams, using observations from two enthusiastically supported college teams. These findings support a "social reinforcement" theory, where audience behavior interacts with task performance, rather than audiences having effects by their mere presence. Since much of the spectator protest was directed at referees, at least some of the home advantage may have been due to referee intimidation by the home crowd.

McGuire et al. (1992) introduce the reverse causal direction in their study of aggression in 840 hockey games. Finding that high levels of player aggression (measured in terms of penalties) boost the winning chances of the home team, they suggest that aggression is used to entice the crowd into more active involvement from which the home team benefits. Visiting teams struggle to leave the home crowd out of the game by checking the escalation of aggression. Since aggressive penalties are remarkably balanced between home and visiting teams, game outcomes are significantly affected by the strategic struggle over mutual aggression levels. This intriguing finding might help account for the across-sport usefulness of crowd intensity in explaining overall home advantage differences, and within-sport difficulties in linking crowd density to any home

TABLE 1: Home Advantage Levels across Sports, in a Composite of Past Studies and in the Present Study

	Composite Home Advantage Results[a]			
Sport	Studies	Games	Home Win Percent	Home Advantage
Baseball	6	23,034	53.5	.070
Football	5	2,592	57.3	.146
Hockey	4	4,322	61.1	.222
Basketball	8	13,596	64.4	.288
		Results for Extant U.S. Major Leagues		
Sport (Seasons)		Team-Seasons	Standard Deviation	Home Advantage
Baseball (1901-90)		1,672	.084	.085
Football (1960-90)		808	.232	.124
Hockey (1917-89)		671	.117	.196
Basketball (1949-89)		636	.129	.290

[a] Source: Courneya & Carron (1992)

advantage. Whether crowds of varying size are activated to produce an effect depends on the dynamics of the competition on the field.

Performance effects of publics cannot be understood in terms of attributes of either publics or competitors when viewed separately. Some researchers, for example, have tried to resolve whether the home team performs better or the away team performs worse before a partisan home crowd. Schwartz and Barsky (1977) looked at both defensive and offensive performance measures in Major League Baseball (such as errors, double plays, runs per at bat) and claimed the home advantage inheres exclusively in offensive superiority after finding the home team had higher levels on offensive performance measures. Andrew (1984) looked at five performance measures in Atlantic Coast Conference Basketball and found significant differences between home and away performance measures in each measure except free-throw percentage. He then used the coaches' "expected" performance levels (in a neutral location?) to determine whether the observed measures were high at home or just low away, claiming support for the latter.

These efforts ignore crucial interdependencies in the sports setting. One team's win is another's loss. A great defensive performance is facilitated by a poor offensive one, and vice versa. Home advantage research often tries to get two pieces of information out of a single performance measure — how "good" each side was in producing it. Instead, publics should be thought of as affecting the nature of the competition between teams rather than the individual playing

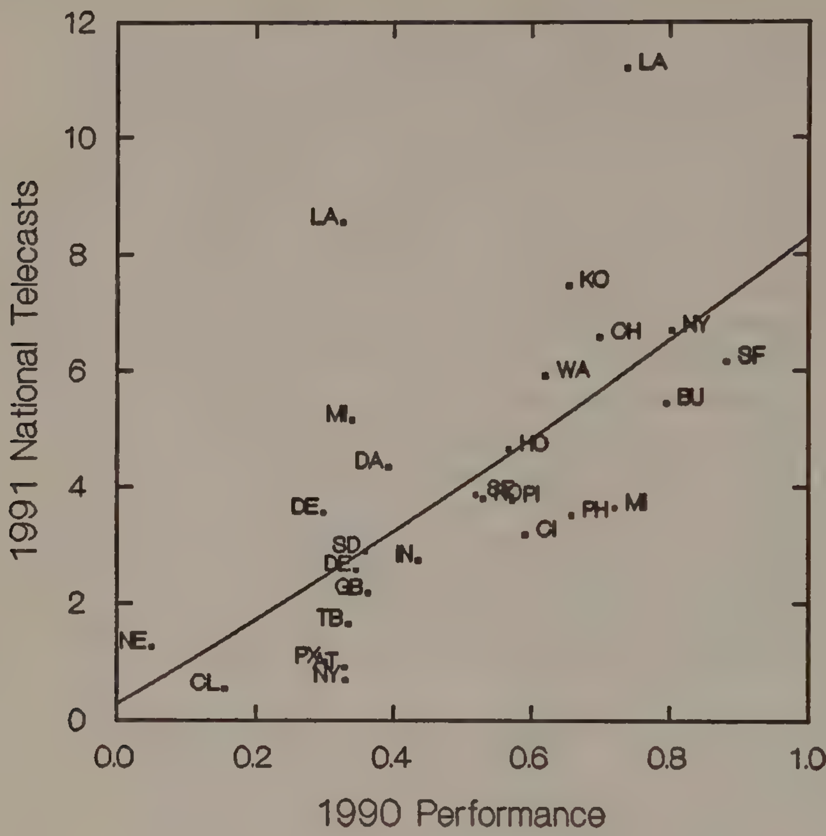
qualities of the teams. Publics don't make teams better or worse; instead, they define the framework in which competition is interpreted and in so doing affect the course of competition itself. This allows the game to be the most basic unit, rather than teams, and allows a clear separation of the home advantage from playing qualities of teams. With this change of imagery, it becomes meaningless to ask which team is affected by a public. Competition is affected.

What interpretive framework is imposed on competition depends on how publics are organized. Home advantage research has acknowledged only one type of public, the partisan local public. Though they may vary in size, involvement, or courtesy, the partisan local public provides unconditional support for the home team. The fact that in every major league sport half of each team's games are played in the same "home" location, before crowds that certainly appear supportive, underscores the importance of partisan local publics. Yet most of those who show up at games, and hordes that do not, are increasingly part of national publics insofar as they tune in to (on television and in print) the same games and analyses as the rest of the nation. Not bound by place, they follow leaguewide competition in search of winners to support. At a game, they can be as familiar with the away team as with the home team and heavily swayed by expectations in their orientation to the outcome. Persisting localism may lead them to want the home team to win, but their grasp of leaguewide competition may lead them to expect the away team to win. This, I argue, will affect the way they behave as publics and their impact on outcomes.

Both local and national publics are creations of leagues, first in attaching teams to cities and then in attaching major league sports to network television. The impact of publics on performance must be viewed in relation to the organizing aims of leagues. The pursuit of local publics created an incentive within leagues to ensure that large-city teams dominated competition, as winning was worth most in the largest local markets (Quirk & Fort 1992). With teams strongly attached to cities, the viability of smaller-city teams has often hinged on the loyalty of partisan local publics persisting despite poor winning chances. Once network television made national publics possible, however, the location of winning teams diminished in importance. Instead of cultivating fan loyalty to a single (home) team, leagues had to lure fans into following leaguewide competition so that fans everywhere might tune into a few selected telecast games. The possibility of national publics made competitive equality a crucial organizational aim for leagues, as it lured fans to search across an entire league for winners to support (Leifer 1995). At the same time, it made winning an imperative for any team seeking to mobilize a national public (Klatell & Marcus 1988; Rader 1984).

As leagues organize competition to accommodate distinct publics, the latitude for these publics to affect competition gets channeled in distinct directions. The loyalty and partisanship of local publics is channeled toward supporting "their" teams. One often hears a sense of guilt among fans if they fail to watch or attend a game involving "their" team, as if their absence could somehow be responsible for the team's loss. Support becomes a show of strength, like foot soldiers behind a mounted commander. If it actually helps the home team win, it would function as a performance leveler, for half of each

FIGURE 1: Relation between the Number of Nationally Televised NFL Games and the Prior Season Performance of Scheduled Teams[a]

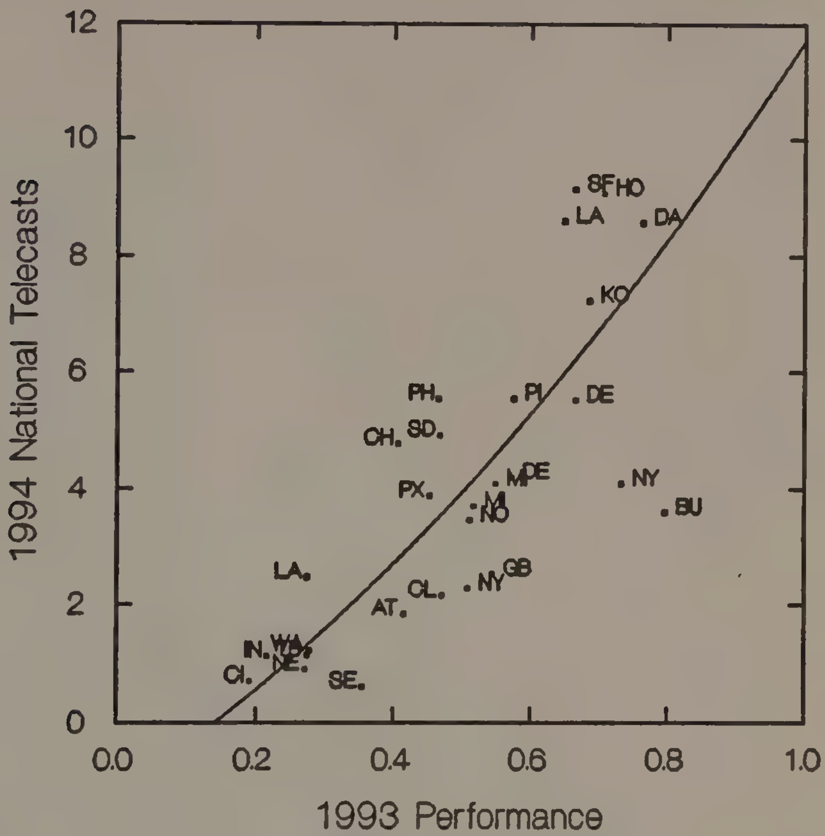


[a] Random noise was introduced to scatter overlapping observations.

team's games are played at home (and half away, where home support for the opponent works against them). Strong teams would be reined in during away games, and weak teams would be boosted during home games. In this way, local publics work against league designs for large-city dominance by hindering strong and weak teams from being strong and weak, respectively, in half the games they play (perverse effect 1).

National publics are not constrained by fixed loyalties. Instead, they cast their support on the basis of performance expectations formed from following leaguewide competition. Past success becomes the most reliable basis for molding these performance expectations. Winning teams amass followings, and losing teams are inevitably abandoned. Winning teams are less supported than adulated, and fans are less foot soldiers than onlookers eager to be associated with the winning side. As can be seen in Figure 1, NFL teams that win in a given season get more national television exposure in the next season. They also get more positive exposure in print and more support from enthusiasts they encounter. Insofar as high (low) performance expectations help a team continue

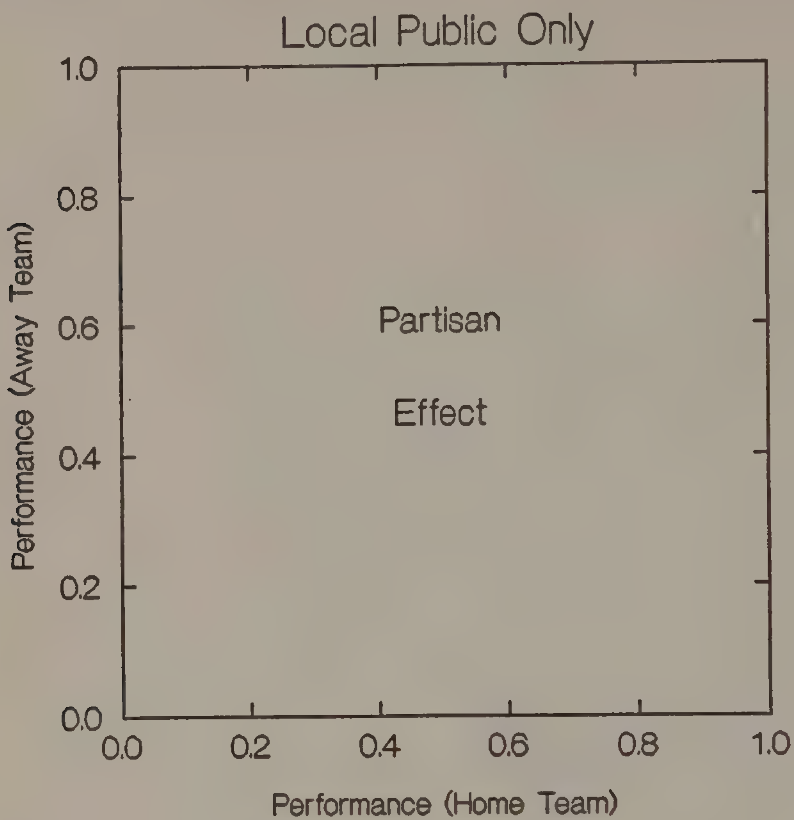
FIGURE 1: Relation between the Number of Nationally Televised NFL Games and the Prior Season Performance of Scheduled Teams[a] (Continued)



winning (losing), they function to induce performance inequalities in what is widely known as a "Matthew effect" (Merton 1957; Podolny 1992). The more successful leagues are in pursuing competitive equality, the more latitude a national public has in inducing performance inequalities, and the more energy it puts into affecting performance outcomes in this perverse manner (perverse effect 2). Real inequality would shut off the national public's influence on and interest in performance outcomes.

In this scenario, publics do not merely follow what happens. They mobilize and react on the basis of an interpretive framework. Where local publics predominate, the failings of a team cannot be divorced from the failings of its local supporters. The show of partisan support among local publics can become as important as the winning and losing of teams. Only where national publics predominate is a relentless zero-sum framework imposed on competition. Every play, every game, and every series is used to sort and resort teams into winner and loser roles. A bit of chance, like a favorable gust of wind or a lucky bounce,

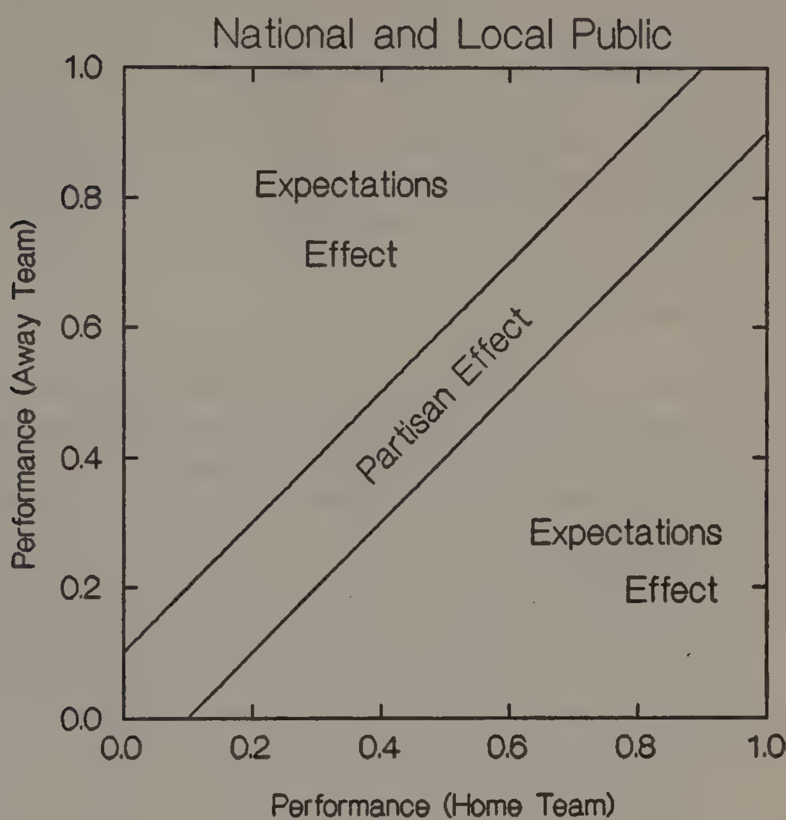
FIGURE 2: Predicted Effects of Publics When Different Kinds of Publics Are Taken into Account



is enough to make two similar teams very different. In the winning locker room after a championship game, it is completely forgotten that only minutes earlier either team could have won.

Major league competition is not intrinsically zero-sum. It can even seem odd that winning and losing are so important in a setting where teams are so much alike. Imagine a world where the public appreciated the competitive balance of teams, getting enjoyment out of the delicate balance maintained by evenly matched teams. The events that led to the breakdown of this balance, that produced a winner and loser, would be viewed as flaws that disrupted the delicate coordination and would evoke disappointment rather than cheers. In this world, public pressure would be directed toward suppressing the emergence of winners and losers, as both would be equated with failure. If we (or major league organizers) look at what fans actually do, instead of their interpretations, this alternative world is not so strange. Fans are quick to leave sporting contests early, or cease following pennant races, when the delicate balance is broken, whether the team they supported is winning or losing. The modern insistence on finding winners and losers only remains viable if leagues work hard to maintain competitive equality. Far from being natural, the zero-sum context national publics impose on competition is antithetical to the basis on which competition is organized.

FIGURE 2: Predicted Effects of Publics When Different Kinds of Publics Are Taken into Account (Continued)



Interpretive context affects competition and not the intrinsic abilities of either home or away teams. Effects will depend on pairings, not on teams. Think of these effects in terms of the performance box with home and away team performance on the axes, as shown in Figure 2. If all publics were local and support for the home team were cast regardless of past performance, then the partisan effect should be uniform throughout the performance box. This is the implicit prediction of most home advantage studies. Where national publics have emerged and influence the orientation of home crowds, the partisan effect should be largely confined to the diagonal of the performance box where no clear expectations regarding the outcome are possible. Off the diagonal, even otherwise partisan home crowds will subtly implicate themselves in outcomes that are perceived as inevitable.[2] As a result, the partisan effect will be diminished and teams will tend to perform as they are expected. In the next section, a performance box is used to examine nonuniformities in the observed home advantage across performance pairings.

The major league sports of football, baseball, basketball, and hockey vary considerably in the extent to which they have been able to mobilize expectation-driven national publics in the order listed (Leifer 1995). Network television broadcasts (for regular season games) are the best indicator for success here. Nearly 70% of National Football League (NFL) team revenues come from an

equally shared network television contract. With a doubleheader on Sunday and a Monday night game, football fans everywhere can tune in to the same carefully selected games. At the other extreme, National Hockey League (NHL) teams depend almost entirely on local box-office receipts and local (and cable) broadcasting rights to survive, ensuring a highly partisan setting (and limited public) for each game. Major League Baseball (MLB) and the National Basketball Association (NBA) fall in between these extremes, with MLB deriving more revenue from network broadcasts than the NBA in the year studied (1980). The differences between sports in the way support is cast are great enough to find distinct consequences of support on performance.

Data and Estimates

Game-level attendance and outcome data was gathered for the 1980 major league season in baseball (2,092 games), basketball (942 games), and hockey (836 games), and, because of the short 16-game season, the 1974-80 seasons for football (1,428 games). The 1980 focal season was selected because it was not disrupted by labor disputes in any of the sports. It also was during the pinnacle of network domination of sport broadcasting, before the explosion of cable, satellite, and pay-per-view options that have since muddied the distinction between local and national publics. Overall, the home advantage was .078 for baseball, .136 for football, .192 for hockey, and .236 for basketball, making the 1980 focal season reflective of the long-term differences between the sports observed earlier.

Game outcomes were used to compute a running measure of performance that corresponds to season standings given in newspapers, from which fans follow the progress of teams throughout the sport season. Game attendance figures (reported in the *Los Angeles Times*) were used to compute crowd densities, or the proportion of each stadium or arena that was filled for each game.[3] To assess the role of performance for mobilizing crowds, particularities of each sport loom large. Baseball teams play 81 home games a season, during days and evenings of every day of the week. Even the most enthusiastic fans must be selective in the games they attend. At the opposite extreme, football teams play only eight home games a season, almost all conveniently scheduled on Sundays. Football often can fill stadiums with season-ticket holders, who commit themselves before the season even begins. To complicate matters, baseball and football teams sometimes share the same stadium, as do basketball and hockey teams, so that stadium capacities often bear little relation to actual ticket demand.

In Table 2, average crowd densities and attendance figures are given for each sport. From these figures alone, it can be expected that football and hockey will show less sensitivity to variations in performance than will basketball and particularly baseball, as stadium size sharply limits the number of people that might otherwise attend games. This sharply truncates the variation in turnout that the various performance combinations would otherwise elicit.

Despite these caveats, home crowds remain sensitive to performance in every sport, as is evident in Figure 3. Categories in Figure 3 are defined by the

TABLE 2: Average Attendances and Crowd Densities for the Four Major League Sports

Sport (Season)	Crowd Density	Attendance	Games (Missing)[a]
Football (1974-80)	.822	54,152	1423 (5)
Baseball (1980)	.414	21,596	2086 (6)
Basketball (1980)	.619	10,005	941 (1)
Hockey (1980)	.840	13,445	834 (2)

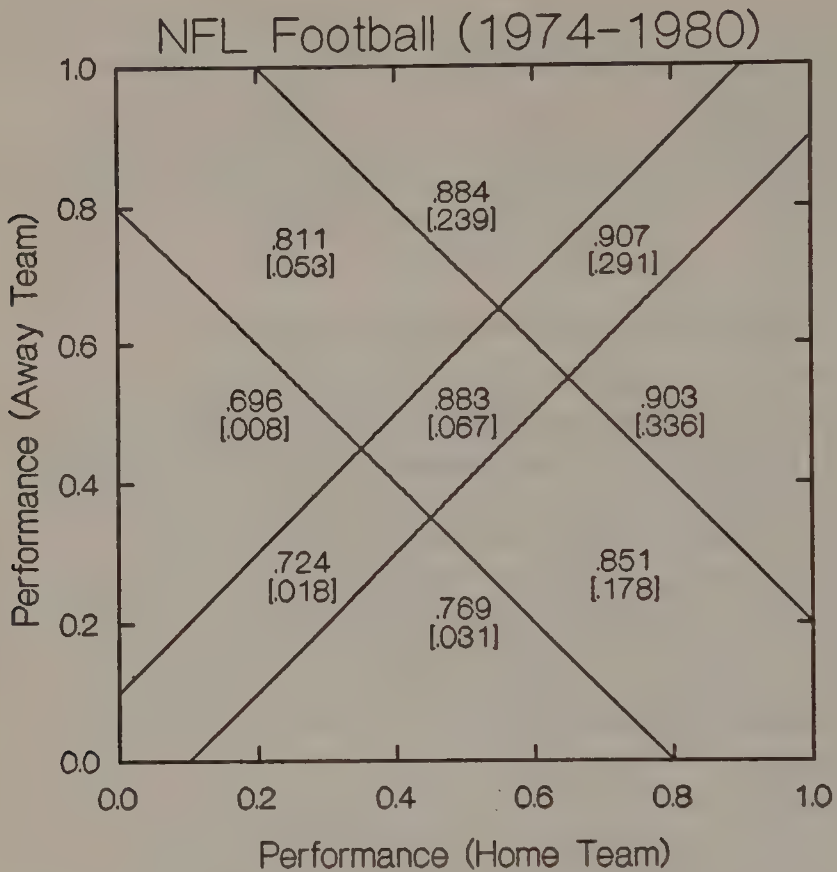
[a] Season games for which no attendance data were available.

relation between the performance levels of home and away teams at the time of the game. From the lower left to upper right of each performance box lie contests where home and away teams had similar performance levels and hence no clear expectations for the outcome were possible. Crowd densities were the highest where both home and away teams were high performers, in every sport. As overall performance levels decline, similarity ceases to attract large publics relative to overall sport averages. In general, local publics are more sensitive to home team performance levels than away team levels, as evidenced from the higher densities in lower right cells than in upper left cells. Proportions of sellouts (density > .98) are given in brackets. These are mostly consistent with crowd density figures.[4]

OLS regression was used to confirm that the pattern in Figure 3 does not depend on the arbitrary categorization of performance or peculiarities in the distribution of stadium sizes. Home and away team performance and their multiplicative interaction, along with stadium size as a control, were introduced into the equation. When regressed on crowd densities, the interaction coefficients were negative in the sports with the highest overall crowd densities. As home and away performance levels rise, increasing crowd density, the capacity cap increasingly comes into play. Where this cap rarely comes into play, as in baseball, the interaction coefficient is strongly positive, indicating that games between high-performing teams have an extraordinary appeal. When the same variables were regressed on the sellout dummy, the interaction coefficients became positive in all sports and significantly so in all but hockey. In no sport except football is the isolated impact of either home or away performance level statistically significant. Nor are intercepts significantly different from zero except in hockey, where sellouts can occur between even the lowest-performing teams. These findings strongly suggest that attendance potential exceeds stadium capacity for games between winning teams outside of baseball.

The same performance boxes can be used to explore the effects of the variable publics on performance. In the context of particular regions of the performance box, the home advantage becomes the difference between home and away winning chances for the same performance combinations at home and away. Home advantage is necessarily symmetrical around the equal perfor-

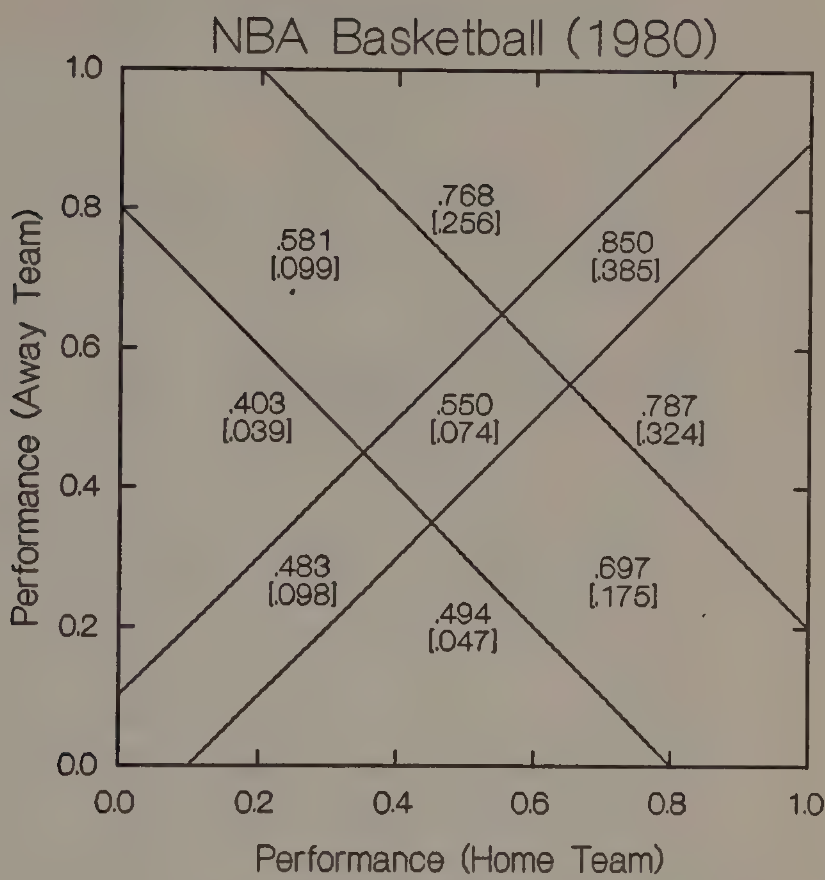
FIGURE 3A: The Effect of Home and Away Team Performance Levels on Average Crowd Density and Proportion of Sellouts[a]



[a] A stricter criterion for similar performance was used for baseball because of this sport's lower level of dispersion in performance.

mance level diagonal, as outcomes on both sides must be used in its calculation. Using a minimum of regions to stabilize estimates of winning chances, Figure 4 shows how dramatically home advantage can vary across performance combinations. Between-sport contrasts are even more striking. Compare, for example, the most nationally televised sport of football with hockey, the sport most lagging in the cultivation of national publics. In football, home advantage is relatively low in games between performance unequals. Among performance equals, home crowds have a sizable impact on helping the home team win and this impact sharply increases as the performance level of both teams rises. Thus there appears to be a parallel between crowd density and home advantage, though the dense crowds that follow winning home teams have little added impact when the home team plays a weaker opponent. As shown in the discussion, stronger teams have similarly high prospects for winning wherever the game is played. Performance expectations prevail.

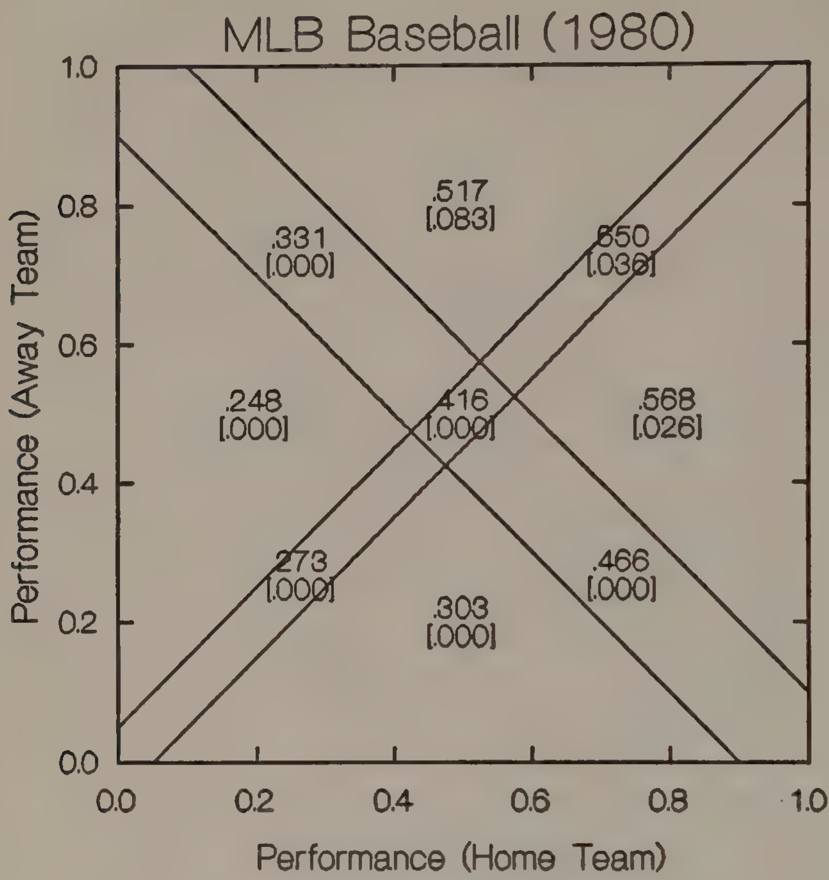
FIGURE 3A: The Effect of Home and Away Team Performance Levels on Average Crowd Density and Proportion of Sellouts[a] (Continued)



Hockey displays virtually the opposite home advantage pattern. Home advantage disappears entirely in games between high performers and increases as performance levels both decrease. In matches between performance unequals, home advantage is relatively high. Though crowds were least sensitive to performance levels in hockey, the fact that a high overall home advantage should disappear where crowds are densest, and appear where they are sparsest (72.3% of capacity) is indeed curious. As developed further below, however, the result is not without function. Local publics, which predominate in hockey, are sensitive to where games are won. Losing teams can maintain local support by winning, albeit rarely, at home. Losses on the road are less debilitating than ones at home, as local publics have themselves to blame for being absent.

Baseball and basketball exhibit curious amalgamations of these extreme patterns. Basketball closely resembles football in games between performance equals and resembles hockey in games between performance unequals. This combination displays the closest parallel with crowd density results. That is, dense crowds appear to magnify home advantage in basketball. For baseball, however, the converse pattern of resemblances hold. Low performers exhibit the

FIGURE 3B: The Effect of Home and Away Team Performance Levels on Average Crowd Density and Proportion of Sellouts[a]

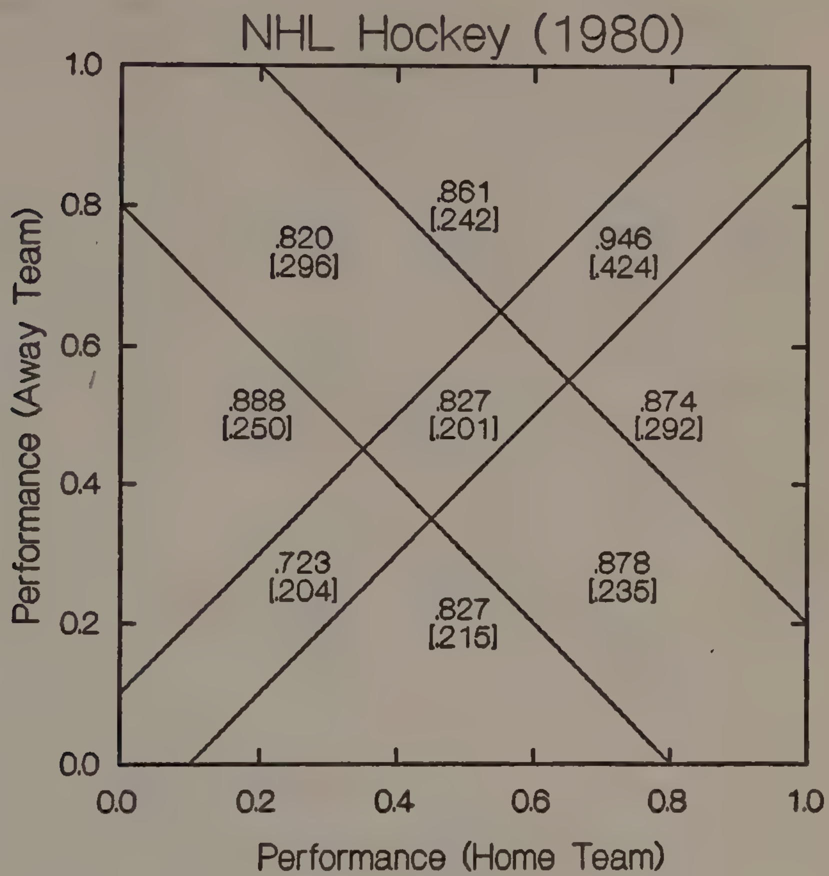


highest home advantage, as in hockey, but unequal performers exhibit relatively low home advantage, as in football. Aside from the slight rise in home advantage in games between high performers, the baseball results are more damning than hockey's for a straightforward crowd density hypothesis, since crowd density was more highly sensitive to performance levels in baseball.[5] Home advantage appears in performance regions where crowds are sparsest in baseball, in sharp contrast with basketball.

Basketball followed a developmental path similar to that of football, remaining primarily a college sport until the modern era, though basketball fell far short of football in cultivating a national public for its regular season play. Baseball shares with hockey a similar developmental path and a continuing dependence on local publics for support, yet it has made more substantial inroads in the creation of national publics. Before trying to link the distinctive role of publics in each sport to its distinctive home advantage pattern, the results need to be further elaborated.

Patterns in Figure 4 are tied to an artificial performance categorization, with some category results based on a relatively small number of observations. As in the crowd density case, regression analysis can be used to test for an underlying

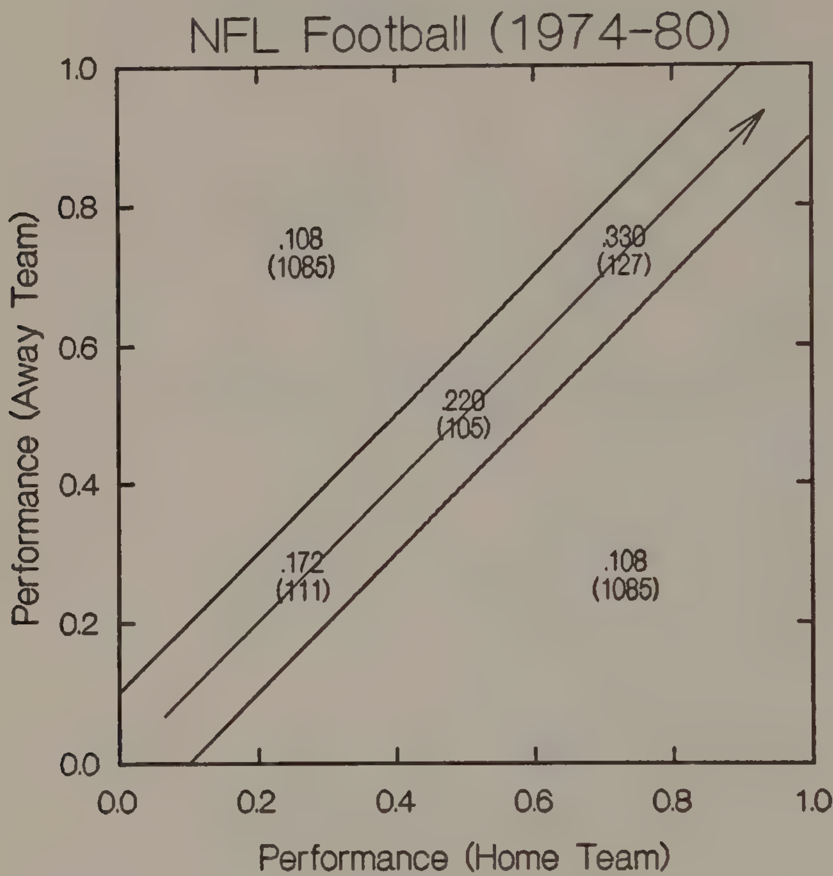
FIGURE 3B: The Effect of Home and Away Team Performance Levels on Average Crowd Density and Proportion of Sellouts[a] (Continued)



logic. In addition, it is necessary to link crowd density, or the lack of it, directly to home advantage patterns. Though in basketball home advantage was the highest in performance regions with the highest crowd densities, for example, the link has not been established at the level of individual games. In any given performance region, actual crowd densities need not be related to home team chances of winning.

To address these limitations, it is convenient to use home team winning chances (HWC) as the dependent variable.[6] HWC is a function of home and away team performance differences, factors tied to the home advantage, and the residual factors of chance and accident. The importance of performance differences can be interpreted in two ways. They may simply be an indicator of skill differences, and hence teams with higher past performance should beat teams with lower past performance. Yet differences would exist even if there were competitive equality and could operate on HWC entirely through the expectations they arouse in both teams and publics. These expectations may subtly modify crowd behavior and the disposition of teams to respond to this behavior. Specifically, national publics should magnify the role of expectations, as they allow visiting teams to be both known and admired by home crowds.

FIGURE 4A: The Effect of Home and Away Team Performance Levels on the Home Advantage. Results Are Symmetrical Around the Similar Performance Axis

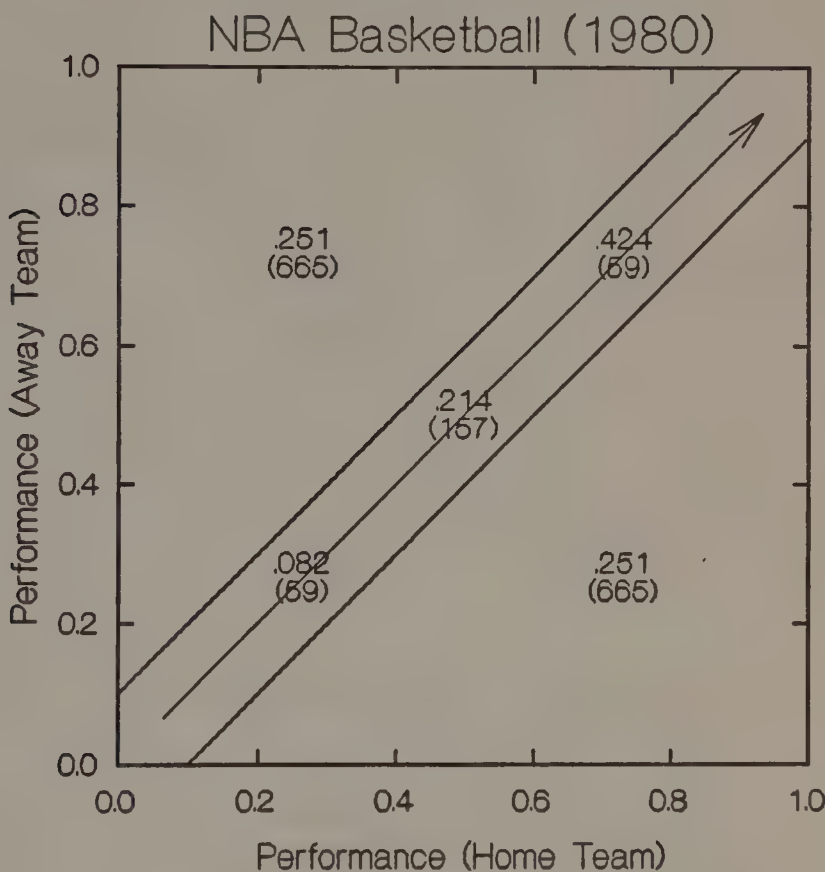


[a] The number of games used to calculate home advantages is given in parentheses.

Hence the fact that higher performers tend to beat lower performers may have as much to do with expectations as it does with skill.

Crowd density and stadium capacity were used as determining factors of home advantage. Since the latter does not vary across games (within the 1980 season) it is only useful for addressing between-team variation. Holding density constant, increases in stadium capacity increase both the absolute size of the crowd and the average distance of the crowd from the competition. These can have opposite impacts on HWC. Yet between-sport differences in home advantage suggest the distance factor may be more important, as sports with the highest home advantage have the smallest and most intimate stadiums. According to the literature reviewed earlier (Schwartz & Barsky 1977), crowd density is supposed to increase HWC when stadium capacity is held constant. To facilitate interpretation, stadium capacities were divided by the largest stadium in each sport, so that the range of both variables falls between zero and

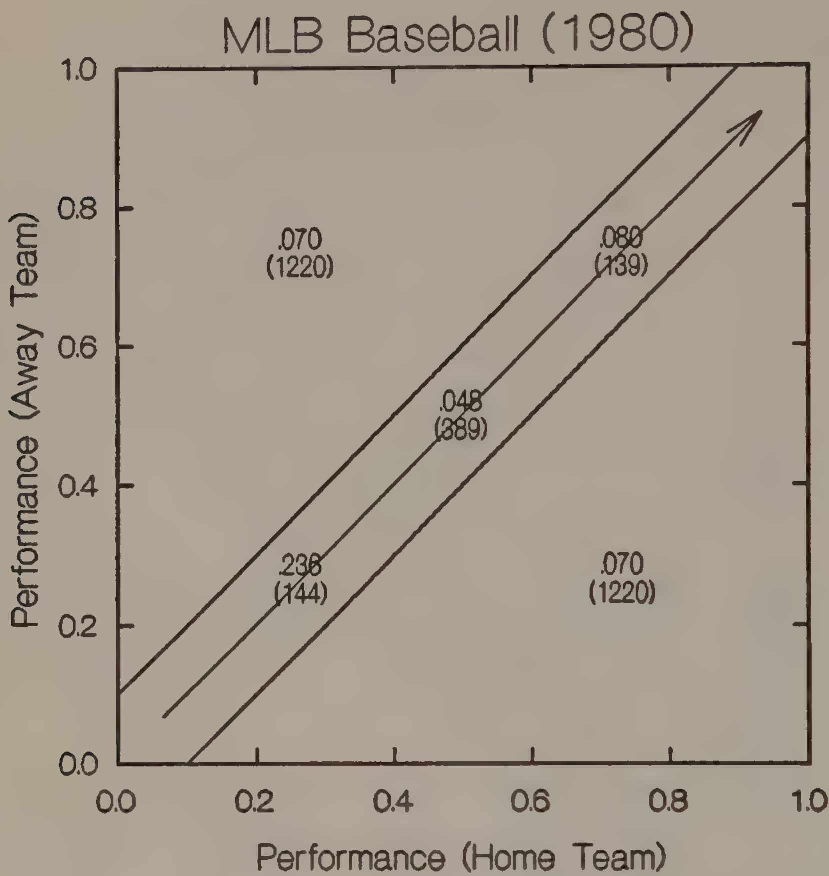
FIGURE 4A: The Effect of Home and Away Team Performance Levels on the Home Advantage. Results Are Symmetrical Around the Similar Performance Axis (Continued)



one.[7] A multiplicative interaction was also constructed, allowing for large, full stadiums to have extra impact, but this was not significant except where noted below.

A two-step analysis was carried out. First, season performance differences (home minus away) at the time of each game were regressed on game outcomes (0 = lose, 0.5 = tie, 1 = win). As shown in Figure 5, the resulting intercepts mirror the overall home win proportions of each sport, which, when differenced from .5, are one-half the overall home advantage. Performance differences show considerable variation in their impact on HWC. In baseball, for example, a home team with an extreme performance advantage of .4 (e.g., .7 to .3) has only a .108 (.4 x .271) better chance of winning than it would playing a team at its own performance level. In basketball, the home team would have a .287 (.4 x .718) better chance in these same circumstances. The overall usefulness of performance differences in predicting game outcomes is measured by the proportion

FIGURE 4B: The Effect of Home and Away Team Performance Levels on the Home Advantage[a]

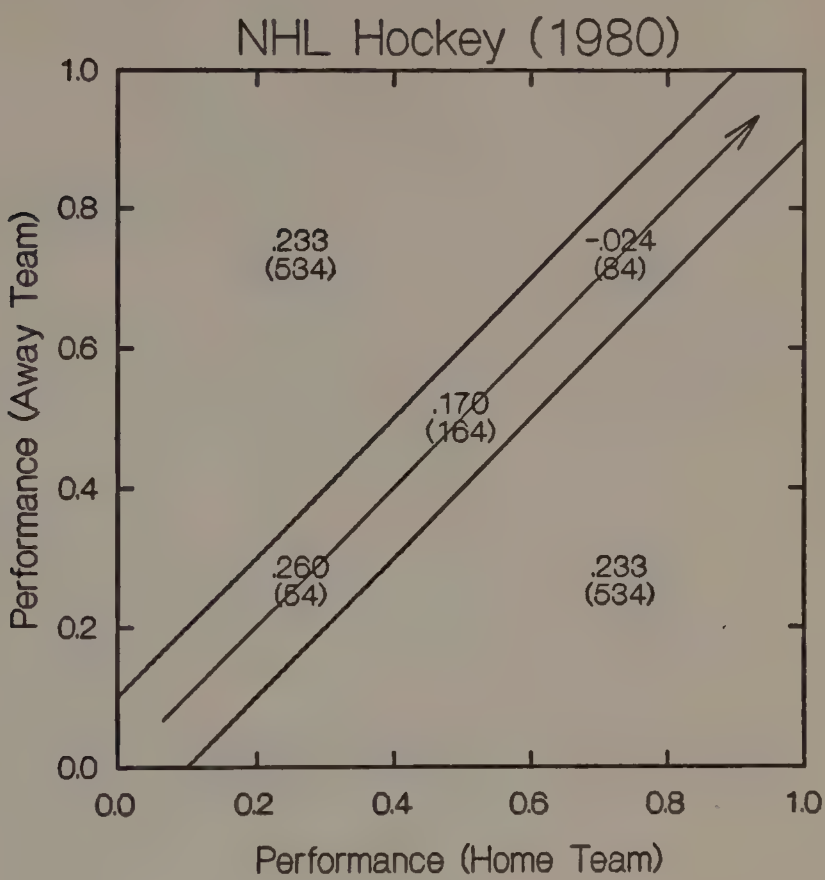


[a] Results are symmetrical around the similar performance axis.

of variation in outcomes accounted for by performance differences, or R^2. This measure varies from .005 in baseball and .078 in hockey to .123 in football and .141 in basketball. If performance were no more than a measure of skill, sports with longer seasons should exhibit higher R^2s, since the measure would on average be based on a larger sample. Yet the results go in the opposite direction, with football teams playing less than one-tenth the number of games that baseball teams do.[8]

Crowd density and stadium capacity were added to the regression equation to account for the residuals.[9] Though the added impact of these variables on HWC was weak, the direction of the impact reinforces the emerging paradox. In football and basketball, home teams had greater chances of winning when denser crowds turned out to support them. Yet the opposite was the case for baseball and hockey, where home teams performed best before the sparsest crowds! In every sport except baseball, larger stadiums decreased home winning chances. A multiplicative interaction term between crowd density and stadium capacity proved insignificant in every sport except baseball, where its inclusion

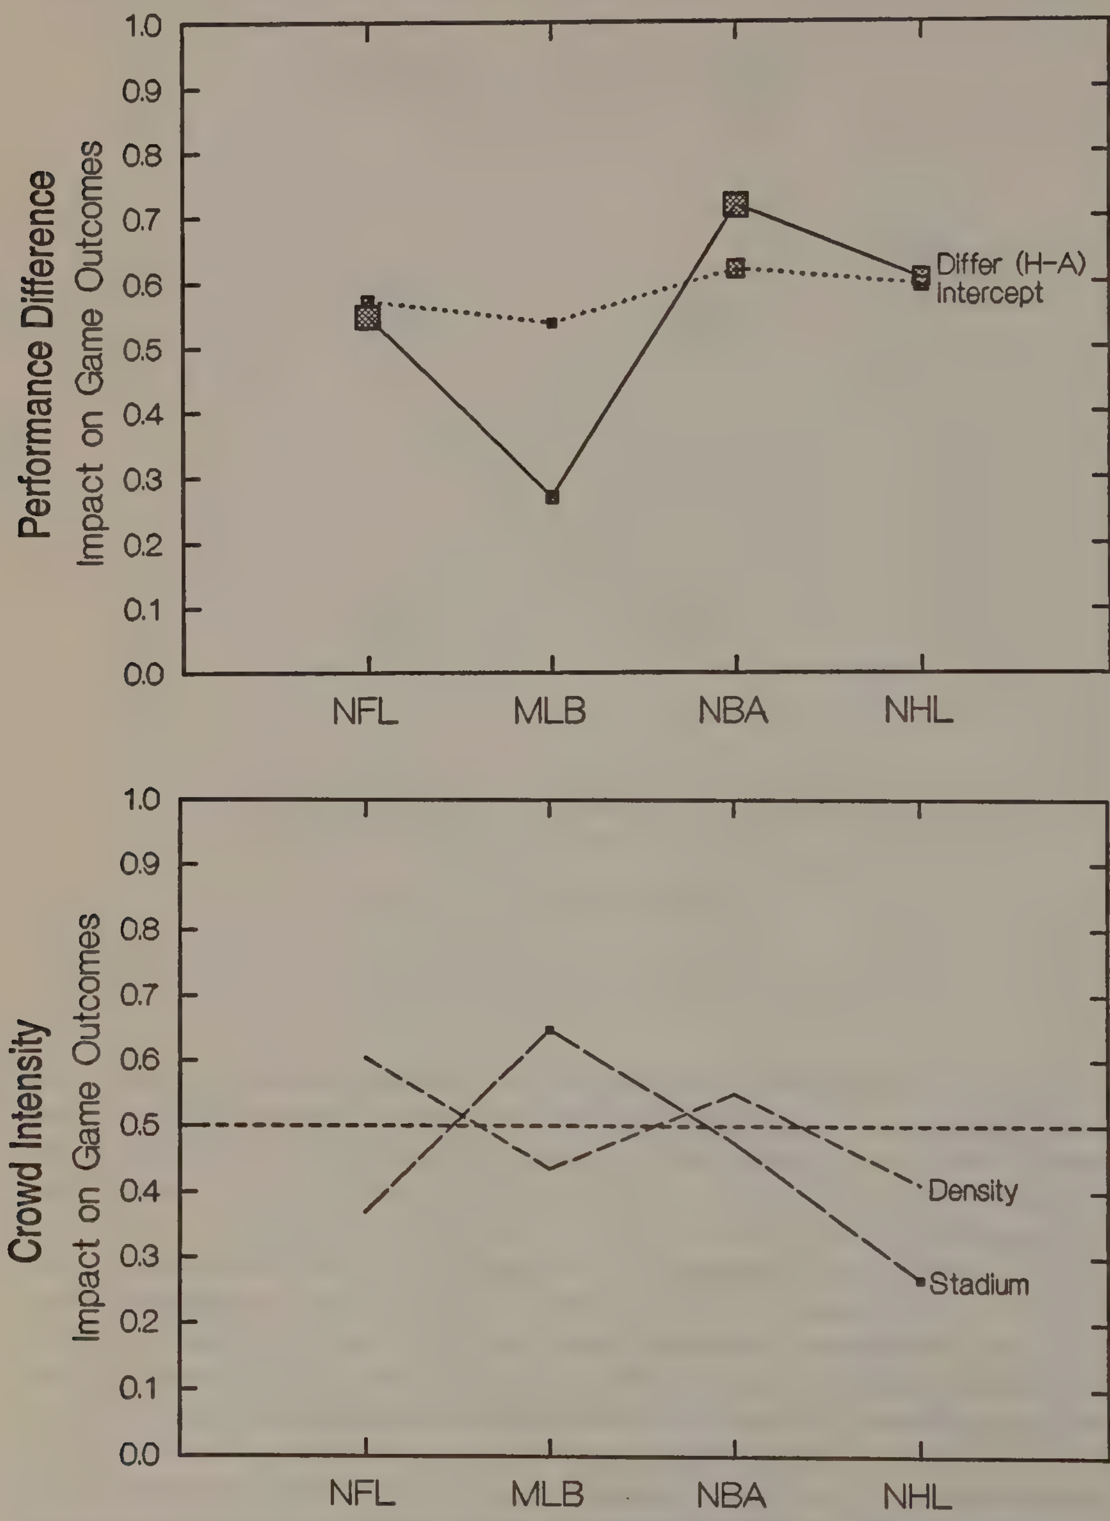
FIGURE 4B: The Effect of Home and Away Team Performance Levels on the Home Advantage[a] (Continued)



both changed the direction of the impact of stadium capacity (to -.157) and made the impact of crowd capacity (-.549) significantly negative. The interaction term, however, had a significant positive impact on HWC (.693), though it was not strong enough to overcome the negative effects of each of its separate components.

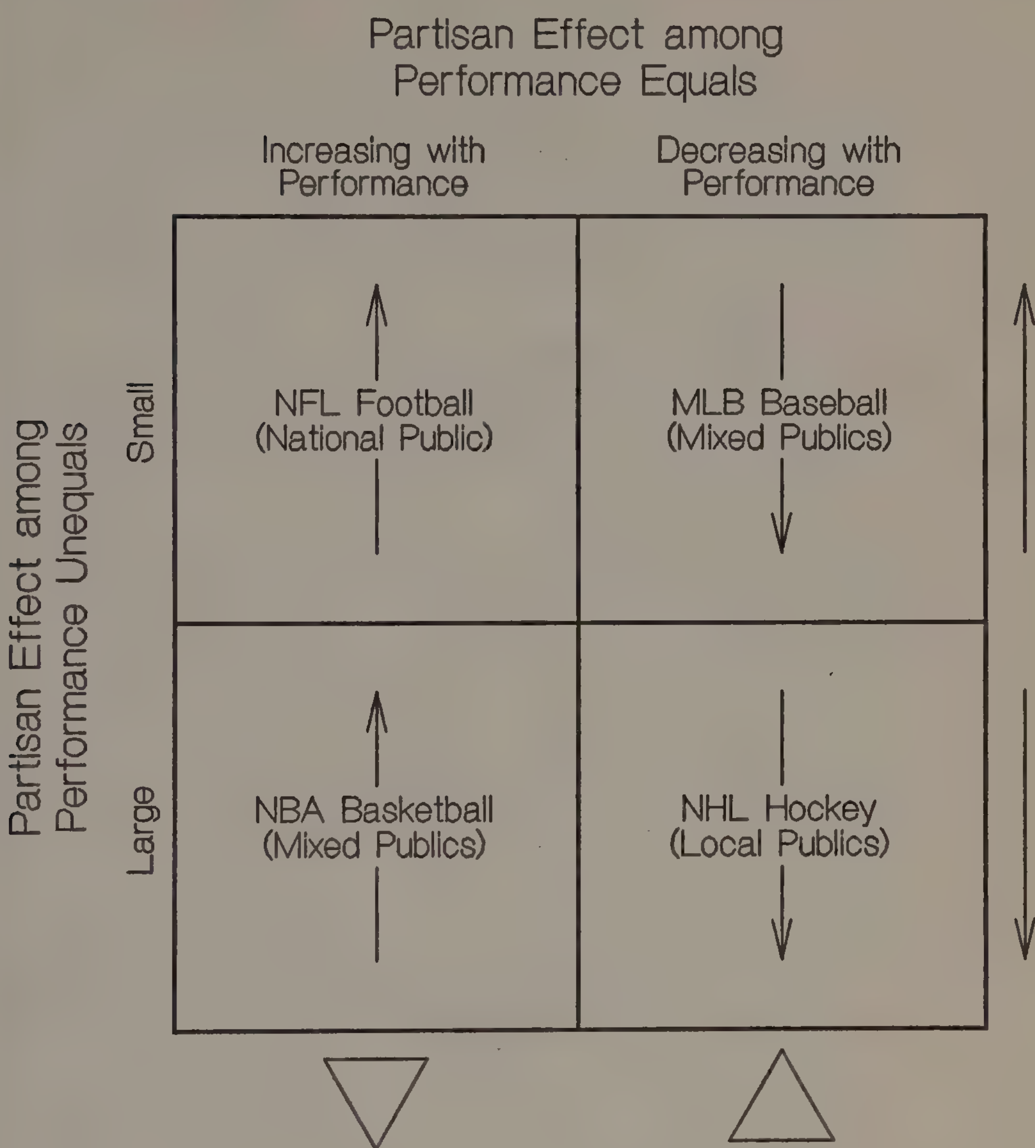
The consistently negative impact of stadium capacity within each sport accords with between-sport differences in overall home advantage. Where stadiums are large and fans quite distant from the competition, as in baseball and football, overall home advantage is lower than in the smaller, more intimate stadiums of hockey and basketball. Stadium variation within each sport is small relative to stadium differences between the sports, and so the fact that within-sport variation still was able to reveal a consistent impact is quite noteworthy. Yet the finding that in baseball and hockey denser crowds of supportive fans can actually lower home winning chances poses a challenge to any straightforward interpretation of the home advantage.

FIGURE 5: Impact Coefficients of Performance Differences and Crowd Intensity Indicators on Game Outcomes[a]



[a] Performance differences were controlled for in the bottom panel results. Size of box denotes degree of statistical significance.
0 = win .5 = tie 1 = win

FIGURE 6: **Summary of Main Findings**[a]



[a] Major leagues differ in the size of the partisan effect for performance equals (columns) and unequals (rows), and in the size of the expectations effect for performance unequals as indicated by arrows through each sport (upward arrows denote a large effect). Since the expectation effect helps magnify performance inequality, and partisan effect lowers it, arrows (in cells and margins) also denote impact on performance inequality. Column symbols indicate whether the column effect promotes performance leveling at the top or bottom of the performance distribution.

Further analysis reveals that crowd density has a different impact that depends on the performance levels of competitors.[10] For both baseball and hockey, crowd density and stadium capacity had their strongest negative, and now significant, impact on HWCs in contests involving performance equals. Among performance equals in football and basketball, large stadiums and dense crowds boosted (significantly in basketball) HWCs (though in football crowds provided the strongest boost for home teams playing higher-performing away teams). In basketball, the impact of crowd density was actually weakly negative in games between performance unequals, confining the positive overall effect entirely to performance equals. Hence crowds tend to have their greatest impact in games between performance equals, though this impact can be channeled in opposite directions across sports.

Figure 6 summarizes the findings in this section. Home advantage patterns reduce neatly to two binary dimensions, with the four sports filling up the four possibilities. Among performance unequals, home advantage was found to be either low or high. Among performance equals, home advantage either increased or decreased with performance levels. Placement on these dimensions appears related to the predominance of national publics in a sport. Football stands in sharpest contrast to hockey with regard to publics, with baseball and basketball treading a middle ground in relying on both local and national publics. Hence the rise of national publics must be associated with low home advantage among performance unequals and increasing home advantage over performance levels among performance equals, as found in football. A third dimension, the impact of performance differences, drives outcomes where home advantage is low. In Figure 6, upward arrows through a sport denote relatively strong impacts and downward arrows denote weak impacts (assessed in terms of R^2s).

All three dimensions have implications for (re)generating patterns of performance inequality. Partisan effects, wherever they appear, function as performance levelers. Hence small partisan effects among performance unequals open the way for the regeneration of performance inequality. Among performance equals, an increasing partisan effect over performance levels will truncate the upper end of the performance distribution, yielding a small group of similarly performing teams at the top (with the opposite pattern yielding a similar group at the bottom of the performance hierarchy). Insofar as performance differences have an impact, they will function to generate performance inequality as winners tend to continue winning and losers to continue losing. The use of up-down arrows (and triangles) in Figure 6 is in reference to these impacts on performance inequality.

In football, for example, winners will tend to split their games among each other, yet for the bulk of games where they play lesser-performing teams they will tend to win wherever the game is played. Hence performance inequality is regenerated among performance unequals yet is clearly capped, as no team will happen to win all its games against other high performers. No such clear cap is induced at the bottom of the performance hierarchy, so some low performers may lose all their games against other low performers. In hockey, these processes are entirely turned around. Low and unequal performers tend to split their games with each other and hence are subject to leveling. Among low

performers in hockey, tendencies to win at home (and reserve losing for away games) may account for the unusually high fan support accorded losing teams. Performance inequality must be generated among higher performers, who win and lose from each other randomly. The resulting lack of close races at the top can serve as an obstacle to cultivating national publics.

Basketball and baseball display peculiar mixtures of effects that represent built-in tensions. Basketball follows football closely, yet both a partisan effect and performance differences effect outcomes among performance unequals. High performers may win nearly all their home games but not much more than half their away games. Performance inequality is generated from the impact of performance differences and suppressed by the partisan effect. For a long time, the bulk of national attention has been focused on two teams, the Boston Celtics and Los Angeles Lakers, and here mainly in the playoffs. If these teams falter, as they have in recent years, the large partisan effect among performance unequals will hinder basketball's ability to produce a new set of nationally hailed winners. In this respect, basketball's situation is more precarious than football's.

Baseball resembles hockey, except it shares with football the weakening of home advantage among performance unequals. Yet performance differences have only a weak impact, so that mostly random inequality is generated from games between performance unequals, as it is in games between equally high performers because of the weakness of the partisan effect. The appearance of a partisan effect among equally low performers functions to truncate the bottom of the performance distribution, yet it is not as effective in bringing out local fans as it is in hockey. Nascent national publics in baseball make overall winning too important for local fans to be satisfied with merely home game wins, yet the predominant localism undermines the impact of performance differences in generating stable winners and losers. Baseball seems to be in the most precarious position of all sports, anchored more by its traditional popularity than by its ability to produce a small group of rival superteams for national publics or a pattern of home game winning that draws local publics.

Simulation Results

Individual games that make up season records are swayed by stellar performances, player injuries, coaching innovations, and a host of other factors we have given no attention to. If in the long run publics have the impact observed in the last section, however, this impact should at least apply pressure for particular patterns of performance inequality to emerge. To isolate these patterns in the clearest possible terms, a computer simulation is used that "plays out" seasons of competition solely on the basis on the effects observed in the last section. These patterns will then be compared to actual patterns, to see how much of observed inequality can be attributed to the complex workings of the partisan and expectation effects.

Driving the simulation is a game outcome equation cast in terms of home winning chances (HWC). To simplify, stadium capacity is assumed to be constant within each sport (and large enough to accommodate ticket demand),

and crowd density is assumed to be entirely a function of contending team performance levels. In addition, a logistic equation is used to constrain HWC between 0 and 1. The resulting equation is:

$$\ln\left(\frac{HWC}{1-HWC}\right) = b_0 + b_1(PFH-PFA) + b_2(equal) + b_3(PFH+PFA)\ x\ equal$$

where

PFH (PFA) = performance level of home (away) team.
equal = a variable equal to 1 if teams have similar (≤.1) performance levels and 0 if not.[11]

In this formulation, b_0 is the partisan effect (i.e., home advantage) for unequal performing contenders, b_1 is the expectations effect, b_2 is the difference in partisan effect between performance equals and unequals (for contending teams with no past wins), and b_3 is the impact on the partisan effect of increasing performance levels among equals. Thus the game outcome equation allows for the effects observed in Figure 5 and summarized in Figure 6. Actual estimates, based on the game outcome data used in the last section, are shown in Table 3. The estimates are consistent with the effects observed in Figure 4, as is the sizable change in game outcome dynamics after midseason in baseball. The stronger expectations effect in the second half of the season may in part be due to a late mobilization of a national public in anticipation of the World Series. With the large number of local broadcasts siphoning off viewership, networks have for a long time been reluctant to nationally broadcast regular season games before the midseason all-star game.

To eliminate the problem of varying season lengths for cross-sport comparisons, a 48-game season was used for all sports. Toward the same end, 28 team leagues with no divisionalization were used for all sports. To assess the effect of these departures from actuality, the league structure and scheduling constraints (including the 16-game season) of the NFL were used in another set of simulations (for all sports). Every simulation was based on 50 seasons of competition. A season schedule was generated by the computer, and its rows and columns were randomly permuted (within divisionalization constraints, if any) for subsequent seasons to guard against scheduling biases (see Leifer 1990b).

No skill differences were admitted among simulated teams. All teams started the simulation as equals (i.e., past performances of .5), and became differentiated only through the workings of the game outcome equation as the season progressed. For subsequent seasons, however, past season performance was "remembered" with a weight of 4 games (2 for the 16-game simulations) among current season results. Hence, after 4 games into a new season, current season standing is equally weighted with past season results, and after 12 games past season results are three-quarters weighted. By the last game of the season, the past season is forgotten entirely. Obviously, without memory, there could be no relation between performances across seasons, as teams would enter each season as perfect equals and initial differences would occur on a purely random basis.

TABLE 3: Estimates for the Game Outcome Equation Used in the Computer Simulation, Based on Actual 1980 Game Outcomes (1974-80 for Football) in the Four Major League Sports[a]

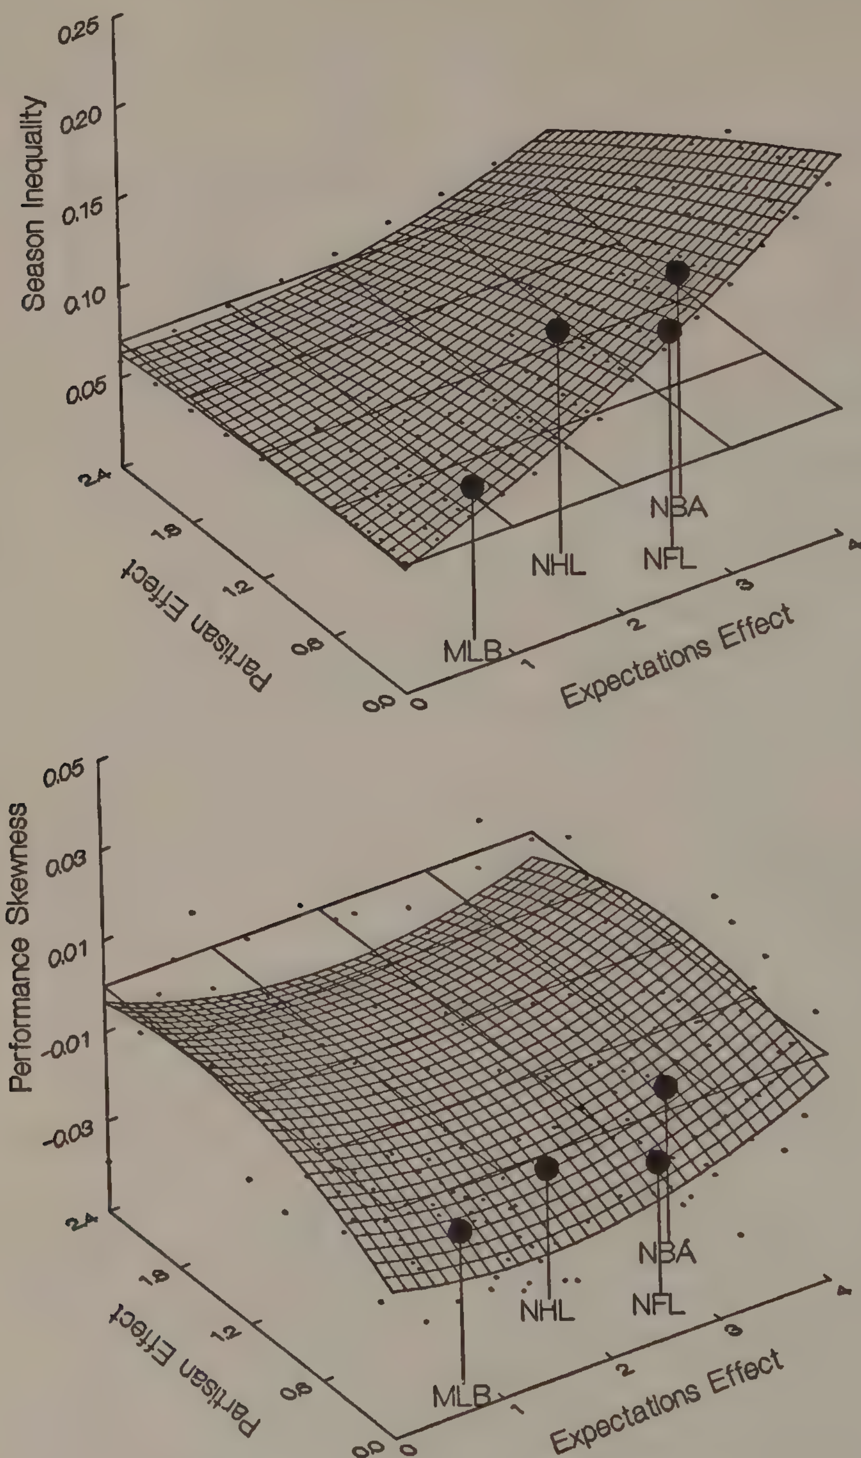
Sport	b_0	b_1	b_2	b_3	Loss Fn
Football	.303	2.437	-.328	.522	661.70
	(.087)	(.266)	(.431)	(.397)	
Baseball (1st half)	.205	.234	.596	-.583	712.80
	(.165)	(.480)	(1.150)	(1.137)	
Baseball (2nd half)	.065	3.216	2.02	-1.902	715.24
	(.220)	(.759)	(1.233)	(1.213)	
Basketball	.641	3.566	-.996	.848	553.06
	(.101)	(.363)	(.537)	(.533)	
Hockey	.525	2.741	.427	-.667	534.68
	(.108)	(.440)	(.643)	(.607)	

[a] Standard errors are in parentheses.

Four measures of performance are monitored, with each measure based on 50 seasons of simulated competition. Season inequality is the average standard deviation of season performances across teams. Performance correlations across seasons gauge the extent to which team performance is stable across seasons (i.e., winners continue winning and losers continue losing). Correlations across both one and four seasons are monitored. Finally, the skewness of the performance distribution is measured by the number of season performances below .5 minus the number above, divided by the maximum possible difference (i.e., one team wins all its games and the rest finish just below .5).

To establish baselines, preliminary simulations varied the levels of the expectations effect ($b_1 \geq 0$) and the constant partisan effect (i.e., $b_0 \geq 0$, with $b_2 = b_3 = 0$). Figure 7 shows the impact of these varying levels on the four performance measures. As the expectations effect increases, season inequality sharply increases over the pure chance level (large grid). The partisan effect operates as a leveler, though substantial results require effects beyond those observed in actual leagues. Similar conclusions can be drawn from looking at inequality across seasons using serial correlations. Correlations spanning four seasons, however, are small even for large expectation effects and small home advantages (this attenuation is largely shaped by memory strength). With no inherent differences between teams (and short memory for emergent differences), national publics can succeed in creating only short-term differences between them. Performance skewness was not systematically related to either the expectation or the partisan effect. Since there is a perfect symmetry between

FIGURE 7A: Simulated Impact of Uniform Partisan and Expectation Effects on Four Performance Measures[a]



[a] Each point used to estimate the fine grid surface is based on a simulation of 50 seasons for 28 competitive equals playing 48 games each. The coarse grid surfaces are the expected results were publics to have no effect on competition.

FIGURE 7B: Simulated Impact of Uniform Partisan and Expectation Effects on Four Performance Measures

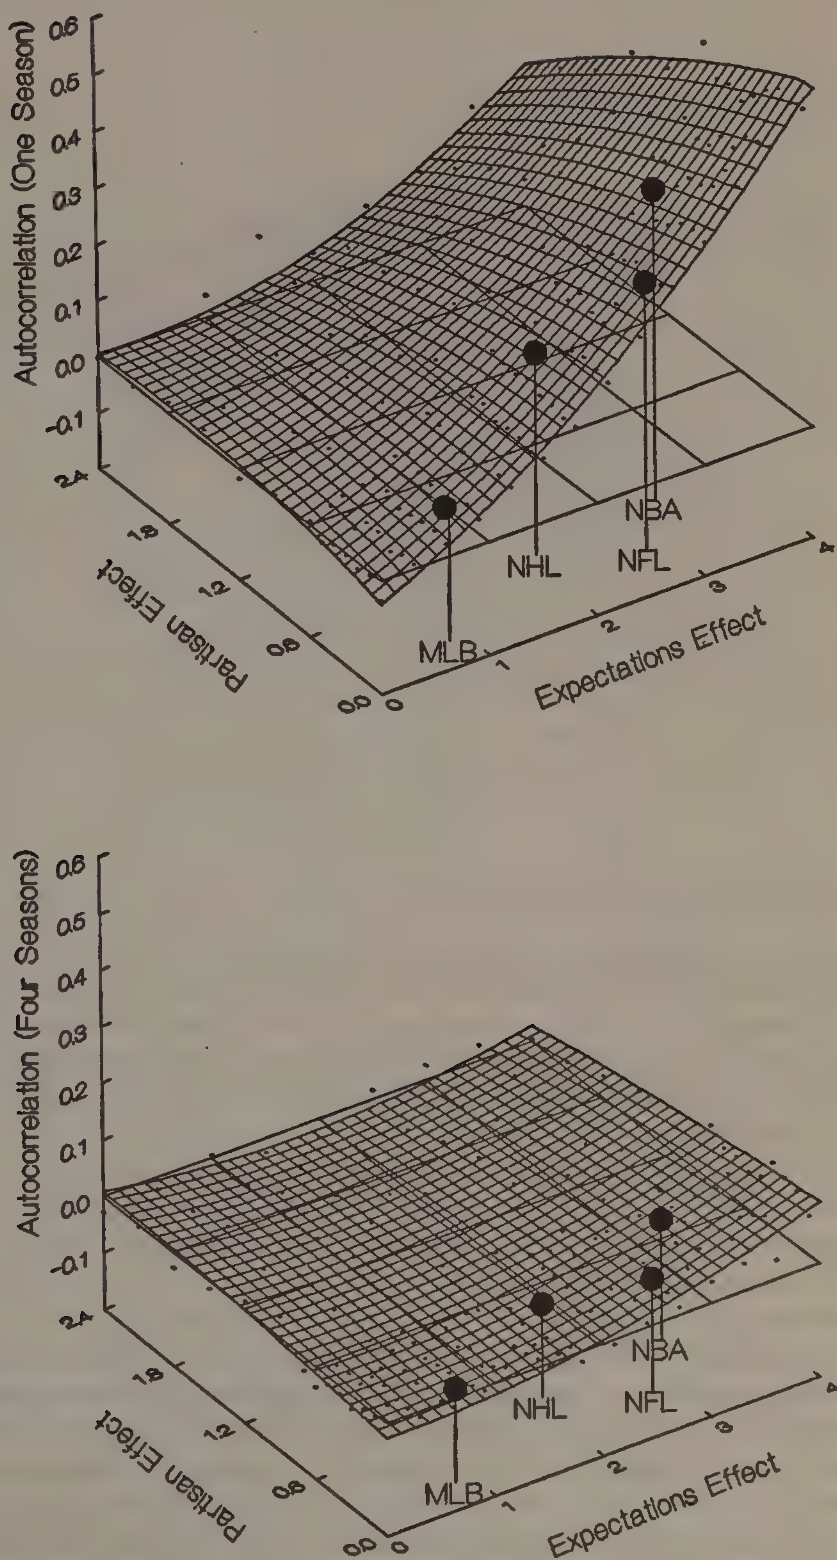


FIGURE 8A: Simulated Impact of Nonuniformities in the Partisan Effect on Performance Measures[a]

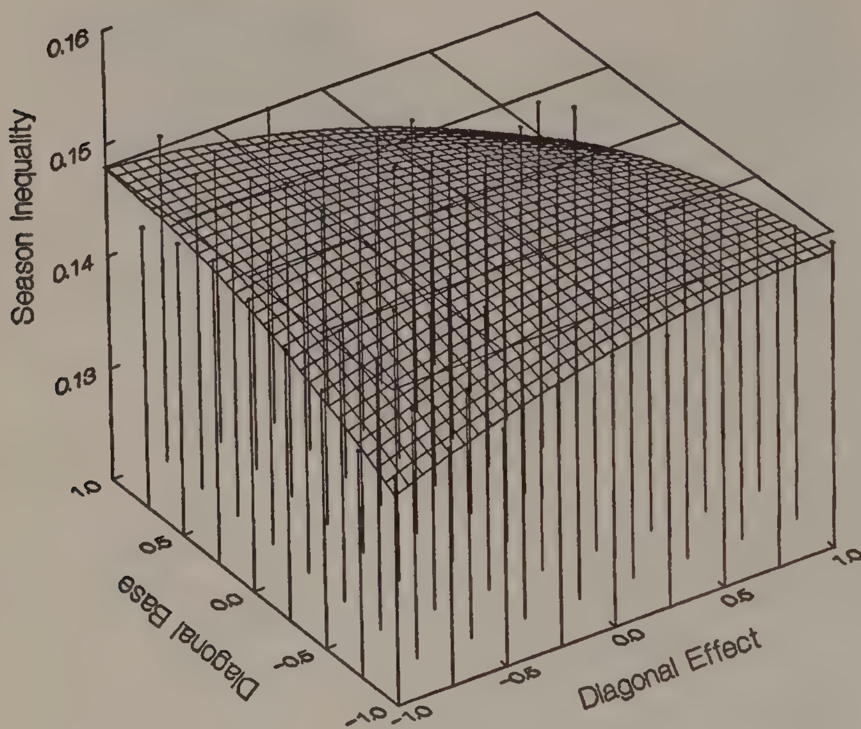
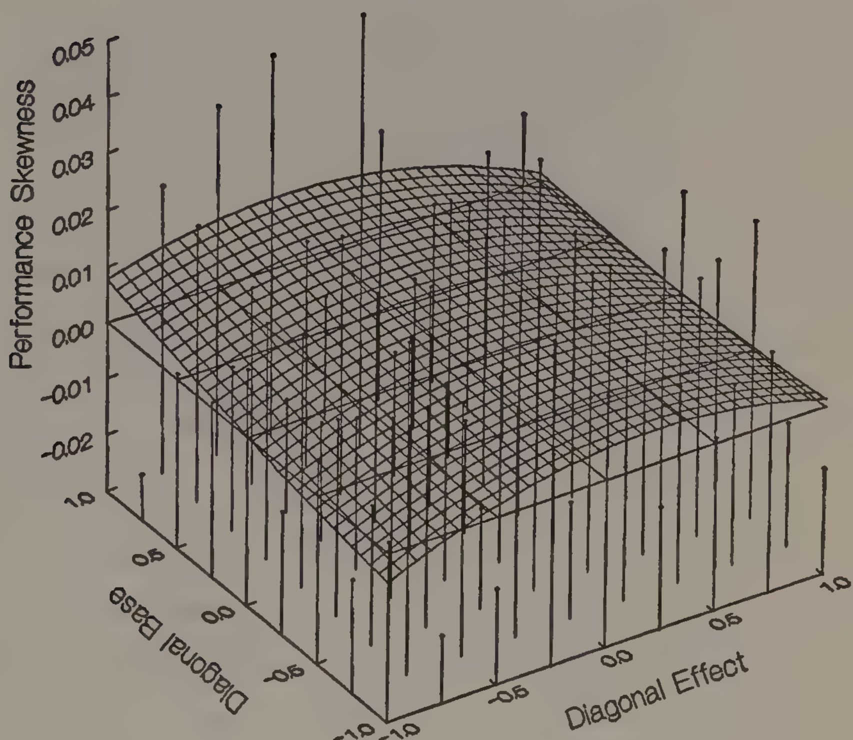


[a] Actual overall partisan and expectation effects from 1974-80 NFL competition are held constant in the simulations (with 28 teams playing 48-game seasons), and partisan effects for similarly performing teams are allowed to vary with performance levels. The diagonal base is the partisan effect for two losing (zero-performance) teams. The diagonal effect is the unit impact of increasing performance levels among similarly performing teams.

high- and low-performing teams in the baseline simulations, there is no reason to expect skewness to be different from zero.

Placing actual leagues in Figure 7 is complicated by the use of a 48-game season. Estimates for the expectation effect (b_1) are sensitive to season length, with longer seasons increasing the effect by enhancing the stability of the performance measure. On the basis of the difference between actual and simulated season length and standard errors, projected (to a 48-game season) estimates for b_1 were 2.750, .788, 3.235, and 1.977 for the sports as ordered in Table 3. A combination of high expectation and low partisan effects generates the most inequality, with the former dominating. Thus if public effects are the

FIGURE 8A: Simulated Impact of Nonuniformities in the Partisan Effect on Performance Measures[a] (Continued)



only thing driving performance inequality, football and perhaps basketball should exhibit the most inequality, and hockey and baseball the least.

Nonuniformity in partisan effects were introduced into the diagonal base (b_2) and diagonal effect (b_3) coefficients, using actual estimates for b_0 and b_1 from the four league sports. The results for football (using b_1 = 2.750) are shown in Figure 8. Since a low diagonal base and negative diagonal effect, and vice versa, will affect the overall home advantage level, attention should be directed to the upper-left-to-lower-right diagonal, along which overall home advantage remains constant. It is disappointing that there is not much going on along this diagonal with respect to the inequality measures. At least within the range of actual partisan effect patterns, the nonuniformities are not sufficient to substantially affect long-term performance inequality. Results for the other sports, which are not shown, lead to the same conclusion.

Skewness results were puzzling. Partisan-effect nonuniformities in football and basketball should have produced negative skewness by capping the upper end of performance and allowing spread in the lower end. Positive skewness

should be found for baseball and hockey simulations, where the high partisan effect among lower performers should produce the opposite pattern of caps and spreads. It appears, however, that the magnitude of the actual nonuniformities was not sufficient to produce these predicted effects.

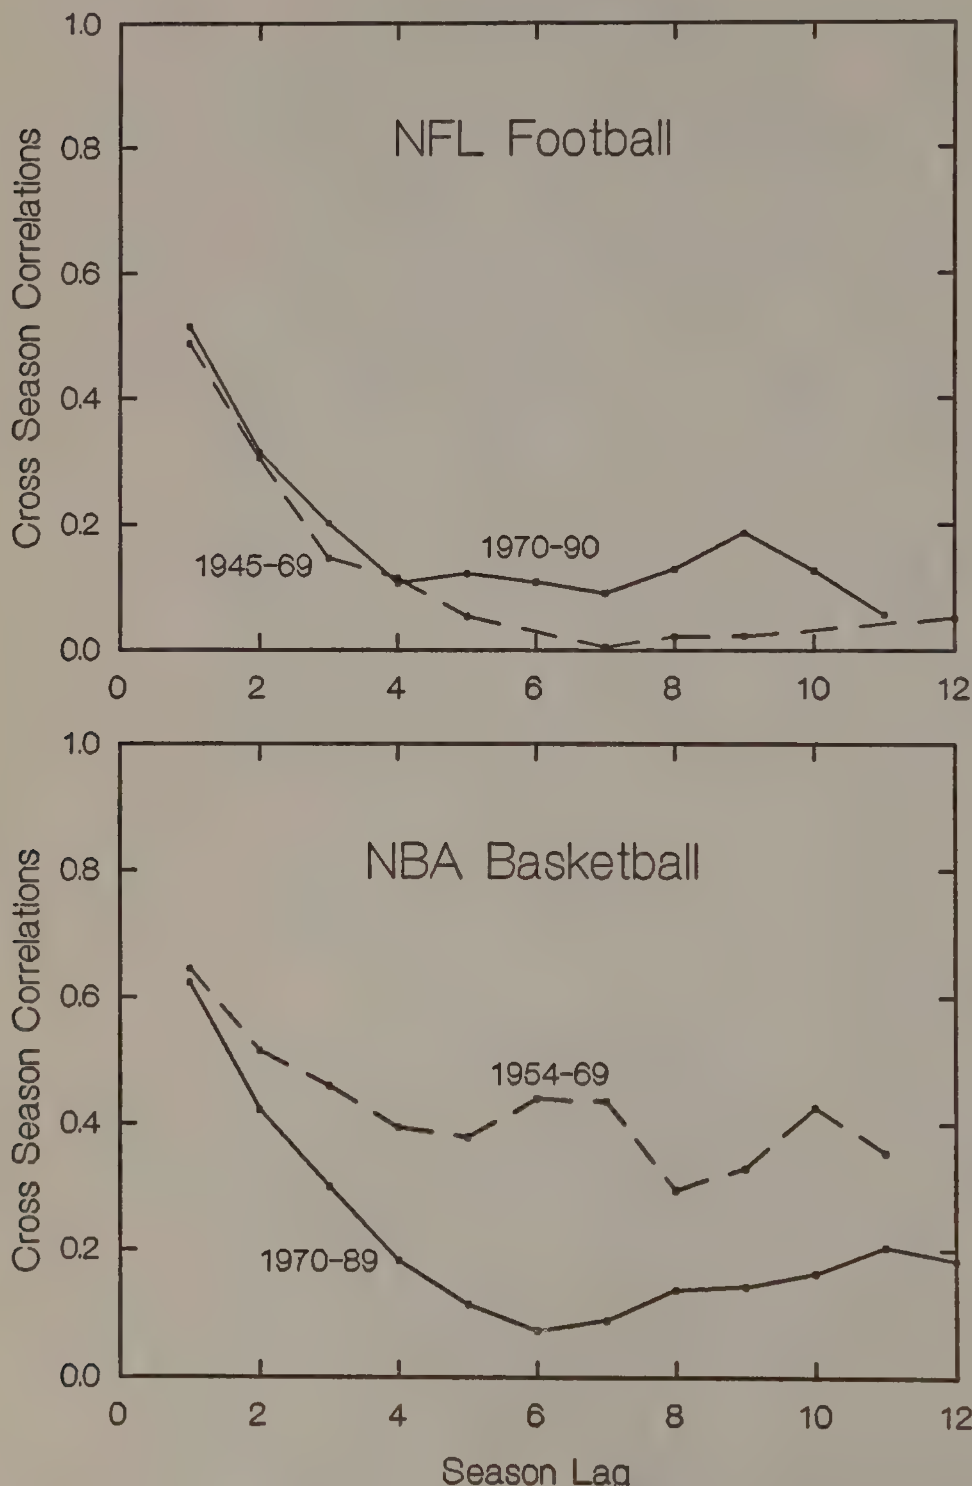
Though the nonuniformities in partisan effects do not appear dramatic enough to affect aggregate performance measures, overall partisan effects and particularly the expectations effect did have substantial effects. Can these factors account for performance measures obtained from the four league sports? Actual performance correlations across up to 12 seasons are graphed in Figure 9. Using the two lower graphs in Figure 7, football results most clearly fit the simulated results for season lags of one and four. Results from simulated 16-game seasons are even more accurate, with cross-season correlations of one and four seasons being .394 and .032 (and a season performance standard deviation of .188, which is within 5% of the actual amount). The other sports, however, should exhibit less inequality than football, since they have either a weaker expectations effect (baseball) or greater home advantage (basketball), or both (hockey). Both baseball and basketball appear to be dramatically moving in this direction considering their much higher inequality in the preceding period, but hockey, with the highest inequality, is moving in the wrong direction.

Missing from the simulation are any factors representing real skill differences between teams. Deviations between the simulated and actual results can be attributed to the persistence of real differences between teams. In this respect, the magnitude of the deviations corresponds closely to the extent to which the sport has entered the modern era of national public cultivation. It is only in this era that true competitive equality has become important, as it induces fans to search broader and deeper for winners than past local loyalties would even allow. In the prototypically modern sport of football, nearly all persisting inequality can be accounted for by the mix of support and expectations that publics impose on sporting competition. The success of the NFL in cultivating national publics has been facilitated by the elimination of real differences between teams. Real differences keep hockey from moving beyond the local loyalties it still depends on.

Performance measures for individual seasons (1970-90) are shown in Figure 10. Season inequality is closely tied to season length in the top panel. Dotted lines provide the theoretically expected inequality were every game to be decided by a coin flip (i.e., competitive equality). Relative to this baseline, results conform to those for cross-season inequality except for hockey, which exhibits less inequality than basketball. Though this may be due to the difficulty of scoring in hockey and the admission of ties (which are numerous), the fact that season inequality is decreasing (A < B) over the period should be noted. On this note, the season-to-season correlations (aggregated in Figure 9) in the bottom panel show the same pattern of decreasing inequality in the 1980s for hockey.

Again, skewness results (middle panel) prove hard to interpret, particularly in the absence of clear simulation results. The 1980 season, used to estimate the game outcome equation, is clearly an outlier for basketball and somewhat for hockey. Basketball shows a clear trend toward negative skew, implying a performance cap that makes for close championship races combined with a

FIGURE 9A: Actual Correlations between Performances in Seasons *t* and *t* lag across All Teams and Seasons within Indicated Periods for Each Major League Sport[a]



[a] Lag periods that bridge a team move were excluded.

FIGURE 9B: Actual Correlations between Performances in Seasons *t* and *t* lag across All Teams and Seasons within Indicated Periods for Each Major League Sport[a]

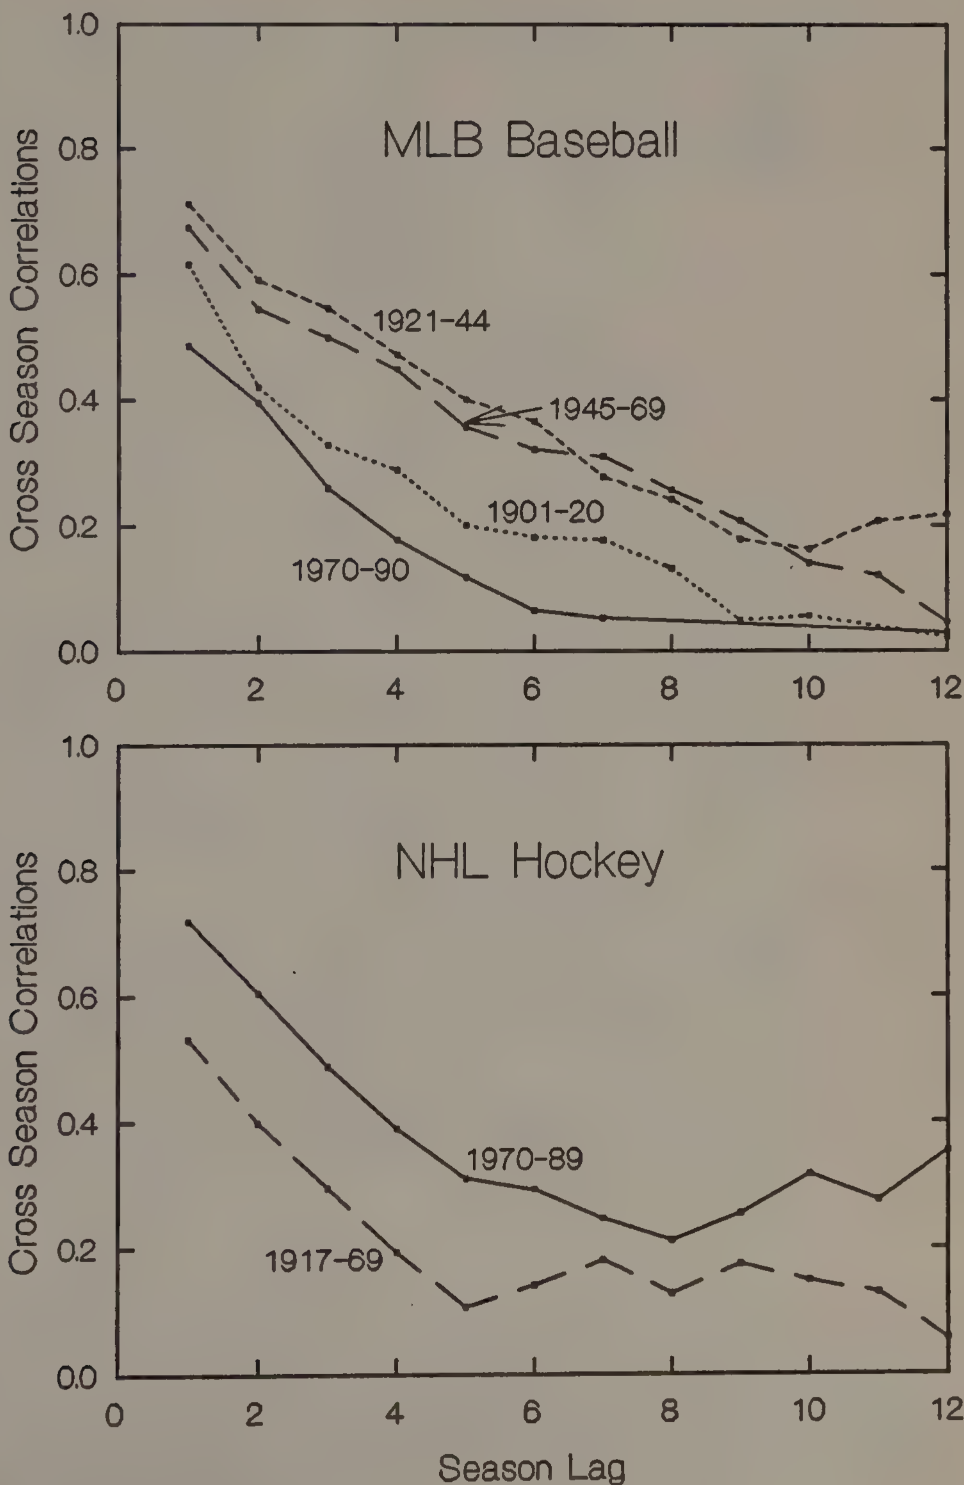


FIGURE 10: Actual Performance Measures for 1970-90 Seasons in the Four League Sports[a]

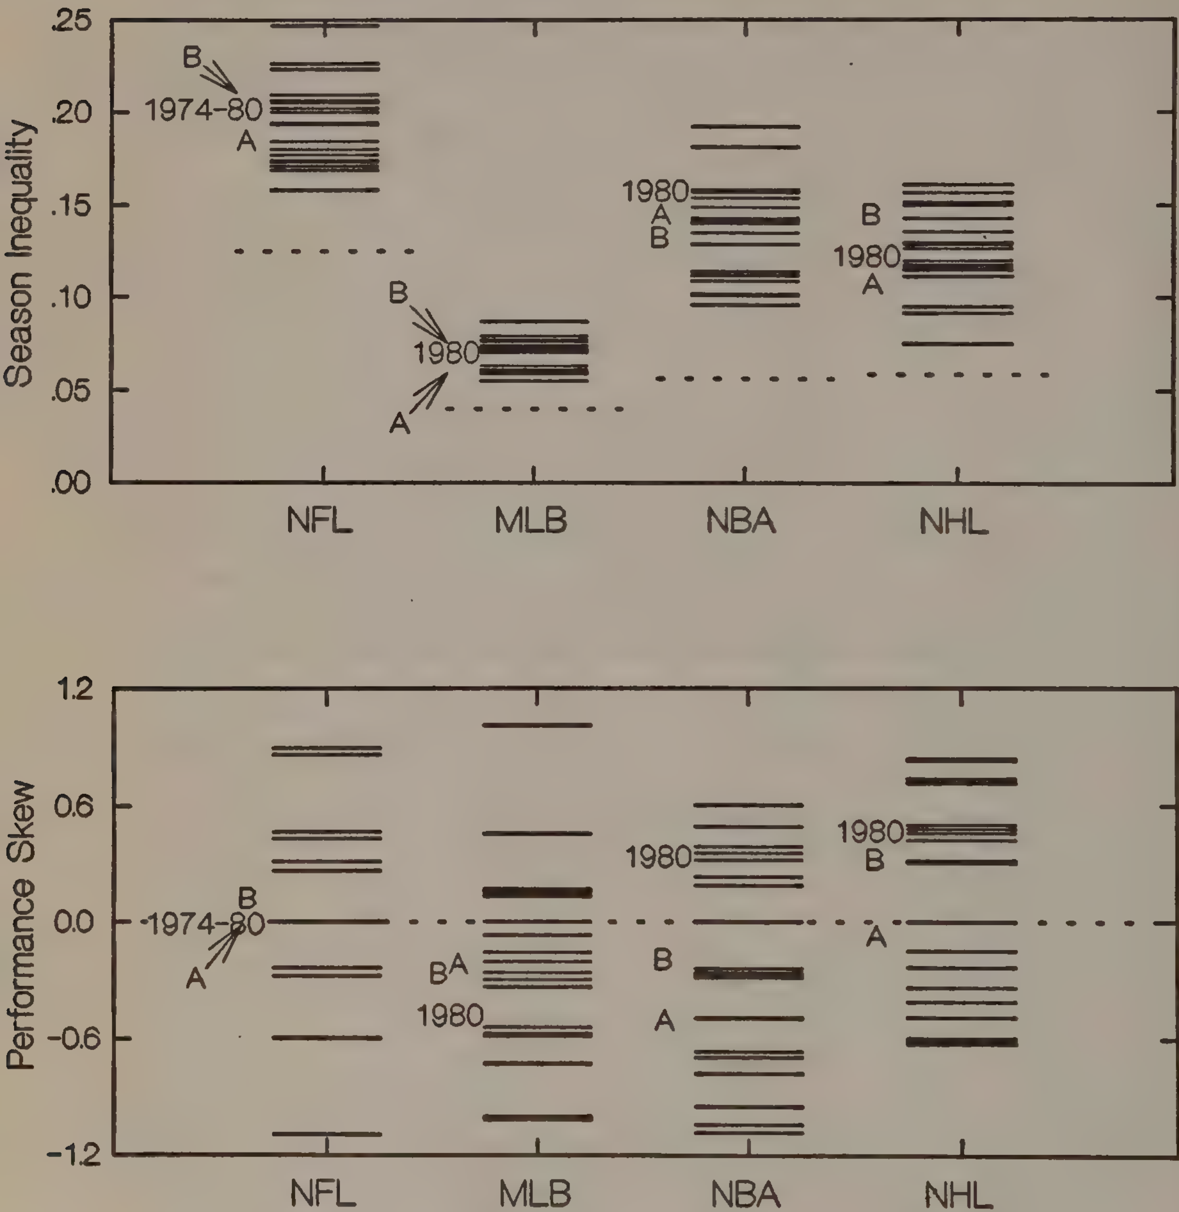
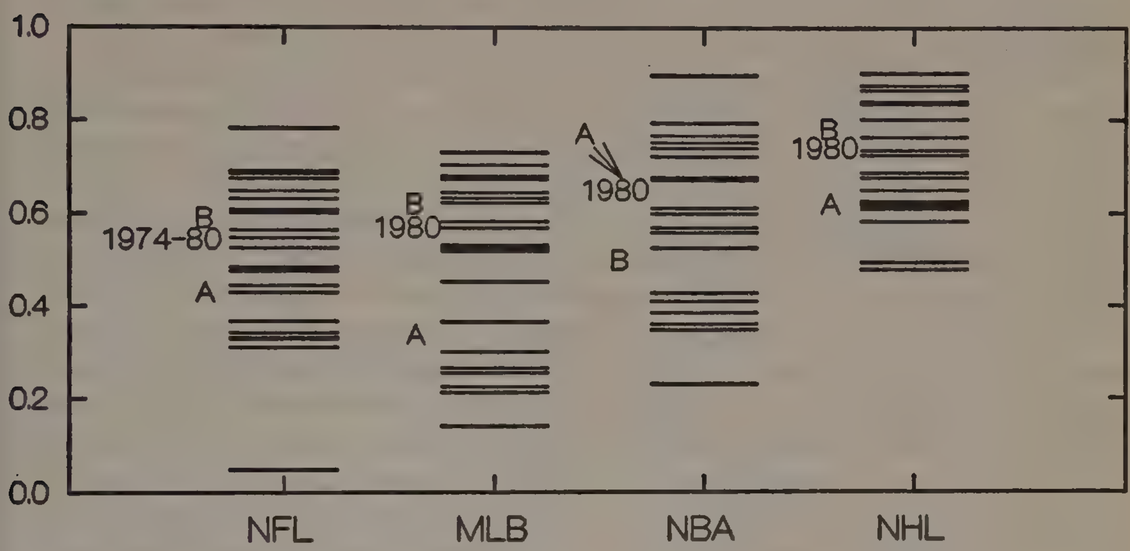


[a] The 1980 season (1974-80 in football) provided estimates for the partisan and expectations effects used in the simulation and is marked along with averages for 1970-79 (B) and 1981-90 (A). Measures in the three panels are those used for the simulation results, except that they are based on individual seasons rather than aggregated data for 50 seasons.

FIGURE 10: Actual Performance Measures for 1970-90 Seasons in the Four League Sports[a] (Continued)



large spread at the bottom of the performance distribution. But this pattern is only weakly found in football, where it was most expected, and the expected converse pattern is not to be found in baseball and hockey. Hence the actual and simulated results are consistent, but both fail to confirm the impact of publics that was predicted before the simulations were run.

In sum, the expectation effect dominated the simulation results, but it could be muted somewhat by a strong overall partisan effect. No clear further impact could be found for nonuniformities in the partisan effect. Performance predictions based solely on public effects were most accurate for football, the sport that has most successfully cultivated national publics. Deviations for the other sports, in the form of real performance differences between teams, varied directly with the progress the sport had made in cultivating national publics. Hence the successful pursuit of competitive equality can be tied to entry into the modern era of national television publics. But the competitive equality remains beneath the surface as national publics induce performance inequality by casting support for winners and withdrawing support from losers.

Discussion and Conclusion

Social support is something that is given and received within an interaction. Both the giving and receiving have consequences not only for those directly involved, but also for those excluded. Because social support involves a taking of sides, it is intrinsically constrained in any given setting. What is given to one side is withheld from another side. The widely observed fact that social support is linked to a diverse array of positive outcomes can lead to misleading recommendations if this constraint is not taken into account. Social support is

sought out and proffered amidst contentions, and every public instance of it marks a defeat as well as a victory.

That social support is received at all is inherently problematic. Even within families, support can be the exception and not the rule, and it can trigger tensions where it is too readily activated, as it is with ailing children or aging parents (Abel 1989; Cooney & Uhlenberg 1992; Hogan, Eggebeen & Clogg 1993). It was necessary, in this article, to look at how competition was organized by major leagues to anticipate where public support for teams might appear and what might be its latitude for affecting outcomes. The central finding of this study is that social support has a perverse effect. It works against the basis on which it is organized. Where major leagues encourage large-city dominance, partisan local publics function as a performance leveler. Conversely, where major leagues pursue competitive equality, expectations of national publics function to induce performance inequality. The more effectively a major league organizes competition for one or the other public, the more effect the publics will have on performance outcomes. No sport has been more effective in cultivating national publics than football, and here we found that the expectations effect could account for virtually all the actual performance inequality. In hockey, still almost entirely dependent on local publics, real inequality persists that a strong partisan effect (especially for low performers) only serves to dampen somewhat.

Organizers and publics are, in effect, locked in an oddly reinforcing antagonism. In sports dependent on local publics, disadvantaged smaller-city teams depend on loyal partisan support to survive in both economic and performance terms. Partisan support helps smaller-city teams win at home and hence directly implicates the local public in performance outcomes. Yet the sizable support that a weak small-city team can maintain only encourages leagues to pursue large-city dominance, as smaller cities would not generate more support by winning than large cities would lose if they failed to win. As long as the attachment between teams and cities remains alive, major league encouragement of large-city dominance merely fuels the need for smaller cities to support their teams, to economically survive and sometimes win.

A dependence on national publics reverses these roles. The more effectively major leagues pursue competitive equality, the more broadly and energetically national publics search for winners to follow. While these publics may appear eager to find real heroes in scouring league competition, the emergence of a truly superior team would dull their interest in the game. Major leagues are typically credited for the great teams they produce, but their policies are directed at spreading talent across teams and not concentrating it within a single one (Leifer 1995). By organizing to reduce real differences between teams, the NFL has allowed publics to freely construct (and deconstruct) the heroes they are looking for. Real performance differences between teams persist in the other sports, particularly hockey, which may only reinforce local dependencies and hinder the emergence of national publics.[12]

Few settings are as tightly organized as major league sports, and hence we cannot expect other types of publics to play as great a role as they do in sports. Yet there are many settings where the dynamics found above have appeared in cruder form. Rosenbaum's (1976, 1984) studies of tracking in high schools and

career mobility in corporations offer intriguing examples. The more care that is taken in either case to place initial recruits on an equal footing, the more energy is spent in finding differences between them once school or jobs have begun. The publics may be partisan on-site teachers or department supervisors, or they may be bearers of universalistic standards lodged in central administration as counselors or personnel experts. This should make a difference in the inequalities that emerge, if anything is to be learned from the present study (Berlew & Hall 1966).

Even where the "design" of a system is purely evolutionary, the complex workings of social support can play a crucial role in shaping inequalities. Cohen (1981), in a study of the Creoles in Sierra Leone, found ambiguities in the definition of "family" that left openings for both partisan and expectation effects. A "cult of the dead" tied the biological offspring of a deceased person together in that property could not be divided among surviving relatives. This became the basis by which lower-status relatives could make claims on higher-status ones. Otherwise, Creoles were endlessly trying to establish "cousinhood" by gaining inclusion into the ceremonials of well-positioned persons (and avoiding lower-status claimants to cousinhood with them). Guest lists throughout Creoledom were closely monitored, for who is in and out in the scramble for advantageous association, with "family" here defined by who showed up at one's ceremonials with gifts of cake and drink in hand. Cohen recognized that the cult of the dead served as a leveler that helped prevent permanent class-based rifts from developing, while the cousinhood dynamics induced pronounced inequalities within Creoledom.

In all the above cases, a random sampling of individuals would confirm that those receiving more social support experienced more positive outcomes. But this finding ignores both the problem of how social support comes to be generated and the perverse effects it has where it appears. In a similar vein, Boudon (1982) has argued that the fact that education is associated with status attainment across individuals does not mean that increasing everyone's education level will increase everyone's status attainment. The workings of social support can be even more perverse in moving beyond the individual level because of the immense significance that social support can have for those who see it being directed toward someone else, with whom they may be contending for status.

Notes

1. Efforts have been made to explain the home advantage in terms that do not directly involve the support of local publics. Travel fatigue among visiting teams is an obvious possibility, yet it fails on close examination. With 162 games played in less than six months, travel fatigue should be greatest in baseball, yet here the home advantage is weakest. Even within (minor league) baseball, Courneya and Carron (1991) found no consistent evidence that travel is a major contributing factor to the home advantage in a detailed statistical examination of direct indicators of travel fatigue (i.e., length of visitor's road trip, length of home stand, series game number, and season game number). The same authors (1990) eliminate a second possibility based on the notion that rules such as the home team's right to bat last in baseball confer an advantage. A learning factor, where the home advantage is traced to the home team's superior knowledge of the local facilities and conditions, has fared little better (Pollard 1986). Baseball

stadiums are among the least standardized of all playing arenas, with different turfs, playing field sizes, wall heights, and local weather conditions.

2. Publics can put pressure on competitors to assume winner and loser roles within a game or pennant race that might not emerge otherwise. Timing is crucial, as stepping into a winner role before it is conferred is strategically unsound. Clausewitz ([1826] 1976) analyzed the weakness of assuming the aggressor role in the absence of superior strength. Before the aggressor-defender roles that lead to winning and losing are assumed, teams must engage in probes and subtle ploys that can themselves conceal opportunities for clear action. Publics can play a decisive part in disrupting the stable equilibrium by latching onto apparent inequalities and convincing both sides of their reality. If partisanship or expectations encouraged one home team into the actions of a winner without simultaneously casting the other team into a loser's role, the actions would backfire. Under pressure from publics, subtle actions give way to actions appropriate to a winner and loser. Without publics, there may be no reliable basis for claiming an advantageous role. For a more thorough discussion of these issues, see Leifer (1988, 1991).

3. Ideally, the size of a stadium would be based on local tendencies to support a home team. If the size of local stadiums stood in direct relation to the size of crowds that would show up for the most appealing games, then actual crowd density would be an indicator of relative appeal. Crowd densities of, say, .6 would mean the same everywhere — 60% of potential support is being tapped by the particular contestants (ignoring consequences of the particular day and time they meet). Unfortunately, the politics of stadium construction do not always yield close fits between stadium size and potential support. Overall, large stadiums prove harder to fill regardless of where they are located or the teams that play in them. Hence in trying to account for crowd density, stadium size had to be (re)introduced as a control variable.

4. In major league baseball, there were only 17 sellouts of which the Kansas City Royals (the pennant winner) accounted for 7 and the Texas Rangers for 4. Though sporadic with regard to home-away performance balance, all sellouts were elicited by games where average performance levels were high.

5. When the National League and American League are analyzed separately, the rise is entirely confined to the NL (.130 vs. .000, respectively), making the phenomenon league-specific. Since there is no reason to expect league differences here, any explanation would be hazardous without more data.

6. The dependent variable is actually game outcomes (code 0, .5, and 1 for losses, ties, and wins). HWC are predicted values. Logistic regression was used in the simulation to ensure that these values do not stray outside the 0,1 range. OLS estimates are used here because they yield similar results and are easier to interpret in impact terms. Home advantage can be calculated directly from the HWCs for performance combinations above and below the equal performance diagonal, and hence factors that affect the latter necessarily affect the former. The dependence of home advantage on outcomes in both home and away locations, however, makes it difficult to analyze directly.

7. During 1980 basketball's Seattle Supersonics played in the Kingdome (where Seattle's baseball team played), which was almost twice as large as the second-largest arena (40,248 versus 22,422). I used the second-largest to scale capacities for basketball and ran analyses involving stadium capacity both with and without Seattle. The text notes where this exclusion made a difference.

8. Within each sport, performance as a measure of skill would imply greater predictive ability in the second half of the season than the first. Yet only in baseball was this the case, with R^2 rising from .000 to .024. In the other three sports, R^2 declined by 15% to 25% in the second half of the season.

9. The use of performance differences (as opposed to using both home and away performance levels), for example, does not allow HWCs to vary along the same performance diagonal. Crowd density and stadium capacity were introduced to account for some of the observed nonuniformities in home advantage. Technically, their influence was not confined to the residuals, since coefficients for performance differences were reestimated with the introduction

of these variables. The coefficients changed very little, however, outside of a slight increase (10%) in the baseball coefficient.

10. When the impact of stadium capacity and crowd density was allowed to vary across performance regions, the impact of performance differences entirely disappeared in baseball. This was not the case in any of the other sports, where performance differences continued to be influential (becoming even more so in hockey and not changing at all in football). While separate intercepts for each performance region could absorb regional variation in game outcomes, the fact that this undermined the impact of performance differences only in baseball is quite puzzling.

11. To eliminate any abrupt discontinuities between equals and unequals, an interpolation between the two levels was used for contenders whose performance levels differed by .1 to .2.

12. Baseball is in a precarious position. Its early attachment to cities was exploited by increasing the number of games per season, to generate more gate receipts. But the large number of games became a liability for cultivating national publics, which requires limiting the number of games broadcast. The recent drift toward greater performance equality is a positive development only if a national public is mobilized and succeeds in inducing performance inequality.

General Social Survey Can Now Be Searched Electronically

The *General Social Survey (GSS)* is now part of the electronic Public Opinion Item Index maintained by the Institute for Research in Social Science *(IRSS)* at the University of North Carolina at Chapel Hill. A national survey conducted yearly by the National Opinion Research Center *(NORC)* since 1972, the *GSS* repeats many questions regularly, allowing researchers to track changes in opinion on a variety of issues. As part of the *IRSS* Index, *GSS* questions and their marginal frequencies can be examined by researchers from around the world via the INTERNET or by phone.

Who Said There's No Free Lunch?

The *IRSS* Index allows any researcher with a modem-equipped PC or connection to INTERNET to view questions and the frequency distributions of the responses for the *GSS*, as well as a variety of state and national polls, including the Louis Harris Polls. The service is free (except for the long-distance charge incurred by modem users). Using the Index, researchers can search electronically for specific poll questions by using combinations of words which occur in the questions. The Index provides quick and easy access for users who want to find previous question wordings in order to develop questions for their own studies, as well as for researchers interested in obtaining frequencies or in locating particular variables for statistical analysis.

More Free Stuff

For detailed information on accessing the item index, performing searches using Boolean search techniques, and printing or using electronic mail to retrieve results, users can obtain the free booklet "A Guide to Searching the IRSS Data Archives" from *IRSS*. To obtain the booklet by mail, send an email message containing your name, mailing address and a request for the "Guide to Searching" to Bonita Samuels at *BSAMUELS.IRSS@MHS.UNC.EDU*. If you wish a copy sent via electronic mail, please mention this in your request and include a complete email address.

How to Access *FREE* IRSS Data Services via the INTERNET

For those who wish to log on using INTERNET, *UNCVM1.OIT.UNC.EDU* is our INTERNET address. After connecting, you will be asked to log on. At the prompt enter a userid "irss10", "irss11" or "irss12". Press return, then enter the password "IRSS". Press return ONCE. You will see "VM read" in the lower right-hand corner of the screen. Press return ONCE and the message should change to "running". (If you get a message that the logon is in use, try another one.) Note: If at any point you see "MORE" or "HOLDING" in the lower right-hand corner of the screen, press the clear key ("Esc ." for VT100 emulation). Next, you will see a screen announcing IRSS's Data Services. From that point on, procedures are self-explanatory.

Any Questions?

For more information about the Public Opinion Item Index or how to get data including the *GSS*, contact David Sheaves at (919) 966-3348, by email at *UIRDSS@UNCVM1.BITNET*, or by fax at (919) 962-4777.

Negotiated Exchanges in Social Networks*

MICHAEL J. LOVAGLIA, *University of Iowa*
JOHN SKVORETZ, *University of South Carolina*
DAVID WILLER, *University of South Carolina*
BARRY MARKOVSKY, *University of Iowa*

Abstract

Network exchange theory predicts relative profits from negotiations among actors in social exchange networks (Markovsky et al. 1993; Markovsky, Willer & Patton 1988). Here we extend the theory to allow exact predictions, rather than merely ordinal, for actors' exchange profits. This is accomplished by integrating two important factors. First, a resistance model predicts bilateral negotiation outcomes within a given set of network constraints. It does so by weighing actors' interests in gaining the best possible exchanges against their desires to avoid the worst. Second, the resistance model predictions are modified by actors' profit expectations. In particular, we incorporate two factors that affect such expectations, both common features of ongoing exchange relations: the number of other actors to whom one is directly connected in the network, and the likelihood of one's completing exchanges with them. We derive hypotheses from the theory and test them in two very different experimental settings. We find that the theory's predictions are more accurate than those of previous versions of the theory and those of five alternative theories.

Social exchange theory grew from the application of the economic theory of exchange to social relationships. Sociology focuses on a problematic area for economic theory: the exchange of valued objects in relatively small groups, where actors seek to settle on one optimal outcome out of a range of possibilities. How can we predict that outcome? And how are such outcomes affected by social structure? Homans (1958, 1974) suggested that principles of behaviorist psychology would help to answer these questions. Blau's (1964) approach used rational choice and utility theory. Theoretical work on the problem since then has largely developed from one or the other perspective, sometimes combining the two.

 Social Forces, September 1995, 74(1):123-55

Both Homans and Blau illustrated their ideas in the context of dyadic relationships. In work settings, for instance, an exchange may entail conferring some reward in return for a costly act. Giving prestige in return for expert help is a common example. Some of these illustrations were quite ingenious. Their very ingenuity, however, convinced critics that the social exchange perspective was tautological and scientifically vacuous. It seemed that any outcome could be explained by a judicious identification of the costs and rewards. This criticism was difficult to overcome as long as the theoretical context remained the isolated dyad. The key to theoretical advance in social exchange was to focus on the embeddedness of dyadic relations in broader contexts. The conceptual horizon has since expanded to incorporate broader relational structures. As a result, social networks have become the focus for rigorous tests of developing theories. These developments were led by Emerson's (1962) seminal work on power-dependence theory. He was the first to suggest specific ways to extend a model of dyadic exchange to larger networks of exchange relations (Emerson 1972). Emerson and colleagues (Cook et al. 1983) later introduced the concept of vulnerability, a measure that predicted which positions in a network structure had power. Vulnerability was based on the idea that some network positions are more important than others in determining the flow of resources through a network. If by removing itself from an exchange a position could reduce the total resources available in a network, then that position had power. The amount of power depends on the disruption in resource flow.

The pace of research on structural power in social exchange networks quickened soon thereafter, spurred by Willer's (1986) critique of the 1983 vulnerability model and a reply by the power-dependence group (Cook, Gillmore & Yamagishi 1986). It was another two years before an alternative formulation was developed that offered better predictions — the network exchange theory of Markovsky, Willer, and Patton (1988). To predict relative power levels for positions in exchange networks, it provided a graph-theoretical power index (GPI) based on a network path-counting algorithm. The theory challenged some basic assumptions of power-dependence theory and withstood critical tests that corroborated GPI predictions and falsified those from the vulnerability model of power-dependence theory.

In 1990 comments and responses pointed out limitations of the GPI (Markovsky, Willer & Patton 1990; Yamagishi & Cook 1990). Soon thereafter, Markovsky (1992) introduced a further refinement, just as power-dependence researchers replaced vulnerability with a completely new algorithm (Cook & Yamagishi 1992). At the same time, three new theories were introduced: Friedkin's (1992) expected value theory, Bienenstock and Bonacich's (1992) application of the "core" from game theory, and Skvoretz and Fararo's (1992) application of Coleman's (1990) rational exchange model. In the next year, Markovsky et al. (1993) identified a new class of structural dynamics and additional refinements in the network exchange theory. Most recently, Skvoretz and Willer (1993) tested the first ratio scale predictions from four theories on a variety of networks. Now, it seems, theoretical developments that once required half a decade occur within a year's time.

Central to theoretical development today is a class of networks in which subtle power differences occur. This phenomenon is known as weak power. In these weak power networks, some positions may have advantages over others in acquiring resources through exchange. However, unlike the advantages in strong power networks, advantages in weak power networks are not progressive. Over a series of exchanges, a strong power advantage eventually results in one exchange partner receiving nearly all available resources. Weak power is limited in range and magnitude. This necessitates theoretical refinement because adequate assessment of power differences between positions in weak power structures requires more precise predictions of exchange rates at equilibrium.

Network exchange theory (Markovsky, Willer & Patton 1988) and its weak power extension (Markovsky et al. 1993) generate ordinal predictions for profits accruing from exchanges among negotiating actors in social networks. The theory is supported primarily by data from experiments in which actors have full information about the shape of the network and know the offers and agreements of all other actors (Skvoretz & Willer 1991).[1] Though the theory is well supported by empirical tests, we make two improvements in the present research. First, we make the theory more precise: By taking into account actors' expectations, we generate ratio-scale predictions. Our refinement predicts exact exchange outcomes. Second, we make the theory more general: We test the theory in a new restricted information setting. Correct predictions for this setting mean we expand the theory's domain of applicability. The theory could then potentially subsume within its scope more social settings in the field — buying a house, for example. When negotiating for a house, a buyer may have little information about the profit her offer will provide the seller and little information about the number and nature of the seller's alternative offers.

Below we review network exchange theory and then describe a new integration of two previous lines of theorizing: the graph-theoretic power index (GPI) for network structures and the resistance model for bilateral negotiations. The extended theory also incorporates biases in actors' expectations induced by the number of their direct ties to other network positions. We first test this new version of the theory against five alternatives with data from full information experiments on four different exchange networks. Finally, the generality of the theory is tested by replicating one of the networks under a new restricted information setting.

Network Exchange Theory

Network exchange theory uses GPI to predict power and profit rankings in exchange networks. Its scope includes networks in which actors in directly connected positions engage in a series of negotiations over divisions of resource pools. Most interesting are networks in which prevailing structural conditions prevent some actors from exchanging at certain times. Such conditions foster power.

GPI: DETECTING STRONG POWER DIFFERENCES

Network exchange theory assumes that GPI can predict power and profit rankings in exchange networks by detecting a position's structural advantage or disadvantage. Here we present an intuitive explanation of how and why it works. The appendix to this article provides a more rigorous treatment.

GPI is calculated by counting paths out from a position in a network. It adds odd-length paths, which are advantageous, and subtracts even-length paths, which are disadvantageous. Odd lengths are advantageous because it means a position has alternatives or a partner's alternatives have alternatives and so on. For example, consider a simple network, three actors connected in a line: A-B-C. Actor A may exchange with B and B with C, but A may not exchange with C. If all actors may exchange only once in a round of bargaining, B gains power because the other actors compete for the single available exchange opportunity with B. We say that B has two 1-paths while A and C have only one. Even-length paths are disadvantageous because it means that a position's potential partners have alternatives that vie with A for exchange with the partners. Actor A has a 2-path through B to C. This is disadvantageous and subtracts from A's GPI score. It means that B has an alternative to exchange with A. Actor B has no 2-paths. Thus the GPI index for the positions in the three-actor line network are 0-2-0. B will have an overwhelming advantage in this network because B has a higher GPI score than A and C. We say that B has a strong power advantage.

Power changes dramatically with the addition of another actor to the above network, making a four-actor line, A-B-C-D (Willer & Patton 1987). Actor A now has a 1-path, a 2-path, and a 3-path. Its GPI score is 1. Actor B now has two 1-paths and one 2-path. Its GPI score is also 1. GPI predicts no strong power advantage for B in the four-actor line network. The reason for this is that the addition of a fourth actor gave A an additional, advantageous, odd-length path, and the addition also gave B an additional disadvantageous even-length path.

GPI extends this analysis to exchange networks of any size and density of relations by counting only nonintersecting paths leading away from a position. Only nonintersecting paths are counted because intersecting paths do not seem to change fundamental power relations in a network. For example, suppose we add a fourth actor, Z, to the three-actor line A-B-C. Actor Z is connected only to B. Actor A now has two disadvantageous 2-paths, one through B to C and one through B to Z. But because these 2-paths intersect at B, the additional disadvantageous 2-path makes no qualitative difference in A's relationship with B. B is still A's only possible exchange partner and B still has an alternative to exchanging with A. GPI ranks the two actors as in the three-actor line. B has a strong power advantage over A, but now GPI scores are more extreme. The GPI score for B is 3 because of the additional 1-path, while for A the GPI score remains 0.

GPI assumes that actors seek exchange with a potential partner who has a larger GPI only if no weaker alternative exists. (Here "to seek exchange" means to make competitive offers, a situation determined only by structural conditions.) Analysis of the Stem network (Figure 2) shows that both C_1 and C_2 have

GPI scores of 1. They will seek exchange with each other but not with B who has a GPI score of 2. The theory assumes that when this happens, GPI is recalculated among the resulting subnetworks of actors who mutually seek exchange. Two subnetworks in the Stem, A-B and C_1-C_2, result; all positions now have a GPI score of 1. No position is predicted to have an overwhelming power advantage in the Stem.

LIKELIHOOD OF EXCLUSION IN WEAK POWER NETWORKS

Markovsky et al. (1993) identify two kinds of power in exchange networks — strong and weak — distinguished by their structural bases and their consequences for exchange profits. The source of power in the two types of network is identical, however: exclusion from exchange. In strong power networks, one or more actors are excluded in every round of exchange by one or more others who, under given structural arrangements, need never be excluded. A position's GPI score encodes its potential to be excluded (or to exclude) relative to its partners. Immediate ties to partners — 1-paths — provide alternatives that enhance a position's potential to exclude or avoid exclusion. This holds for all paths of odd length. But partners' immediate ties to others — 2-paths — provide one's partners with alternatives to oneself and thus decrease a position's potential to avoid exclusion or to exclude. This holds for all paths of even length.

The idea behind weak power is that no position can consistently exclude another without incurring costs to itself (Markovsky et al. 1993). In most weak power networks, either all positions are prone to exclusion or no position is necessarily excluded.[2] That is, for each position there is some outcome in which it is excluded from exchange or it is possible for all positions to be included in exchanges simultaneously. GPI registers these conditions by assigning the same score to all positions and thus predicts no strong power differences. However, GPI measures a position's susceptibility to exclusion on the basis of the pattern of ties alone. Markovsky and associates' (1993) weak power extension to network exchange theory takes account of other factors, in particular the pattern of activity in these ties that could induce differential susceptibility to exclusion.

In strong power networks, profit distributions approach maximum differentiation where the advantaged actors earns between 90% and 100% of available profit. In contrast, profits in weak power networks are more sensitive to actors' strategies, and profits from exchange stabilize well short of maximum differentiation. Generally, the advantaged actor in a weak power network earns between 51% and 75% of available profit. The different levels of profit differentiation between strong and weak power networks reflect the different bases for excludability — i.e., the pattern of ties versus the pattern of activity in those ties.

For example, the Stem is a weak power network. With strong power, profit distributions approach maximum differentiation. That is, if actors negotiate over the allocation of a resource pool containing P units, profits for high-power actors will approach P and those for low-power actors will approach zero. In contrast, profits in weak power structures are more sensitive to actors' strategies, and profits from exchange stabilize well short of maximum differentiation,

e.g., at $(P/2) + 1$ for the advantaged actor, and $(P/2) - 1$ for the disadvantaged actor. In general, structurally disadvantaged actors face more exclusions from exchange than advantaged actors, and when excluded they respond by making offers that slightly favor actors in advantaged positions.

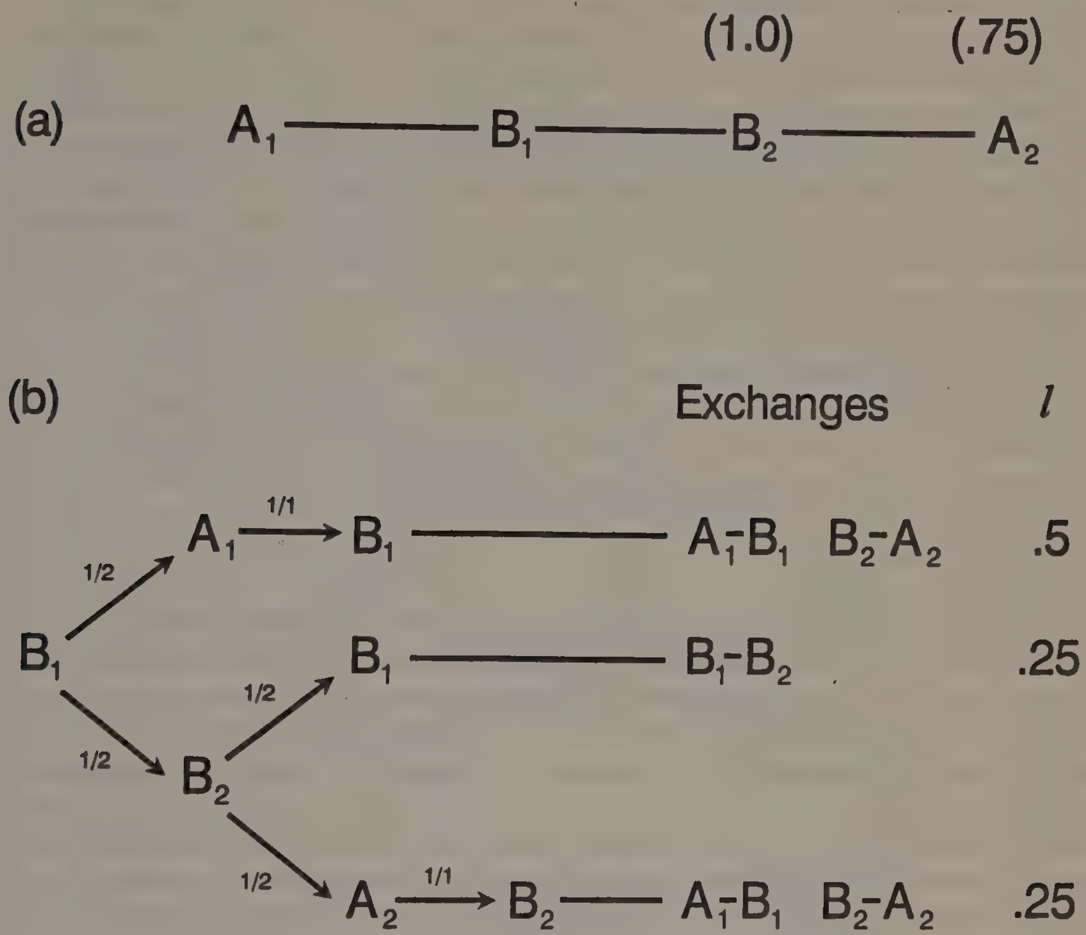
The Markovsky, Willer & Patton (1988) GPI model correctly identified strong power structures in all its tests. That is, (1) unequal GPI values correctly anticipated unequal profits, (2) such profit inequalities were relatively large, and (3) whenever profit levels were equal, then so were GPI values. However, Skvoretz and Willer (1991) found that actors' profits may differ even when their GPIs are equal. Prediction of these profit differences required a second step taken in Markovsky et al. (1993): When all GPIs are equal, each position's likelihood of being included in exchanges, l (or of being excluded, $1 - l$), is calculated under the assumption that actors have no preferences among partners.[3] Then, in an i-j relation, actor i has weak power over j only if GPI values are equal and if $l_i > l_j$ (see Appendix). Otherwise, $l_i = l_j$ and i and j are equal in power. Thus, likelihood of being included detects weak power in networks where GPI detects no strong power differences. The analysis of l_i is not applicable in strong power structures, but rather GPI is used to predict the very robust profit differences that occur there. In summary, we detect power differences in two steps. First, GPI is applied to find strong power differences. Second, where no strong power differences are found, likelihoods of being included are calculated to assess any weak power differences that may exist.

As an example, consider the four-actor line of Figure 1A. GPI = 1 for all positions. Because positions have equal GPI, no strong power differences exist. Therefore, we turn to calculation of l_i to check for any weak power differences. In this network, A_1 can negotiate and exchange with B_1; B_1 may do so with A_1 or B_2; and so on down the line. Assuming that each actor can exchange only once per round and is indifferent to with whom, either B has a .5 probability of seeking exchange with an A and a .5 probability of seeking exchange with the other B. The probability that an A will seek exchange with a B is 1.0 because the A's have no alternatives.

Figure 1b shows a probability tree used to calculate l for each position. Each branch of the tree shows an exchange-seek and its associated probability. The Exchanges column shows mutual exchange-seeks and the l column shows the product of branch probabilities leading to each possible exchange. The likelihood of exchange between two actors is the sum of the probabilities associated with their mutual exchange-seeks in the Exchanges column. An actor's likelihood of being included in any exchange is the sum of the probabilities associated with all exchanges that include that actor. From the tree we derive that $l_{AB} = .75$ for both A-B pairs; $l_{B_1B_2} = .25$; $l_A = .75$; and $l_B = 1$.

The foregoing procedure generalizes to more complex networks and to networks where actors can exchange more than once in a round of bargaining (Markovsky 1992; Markovsky et al. 1993). The distinction between single and multiple exchange is theoretically important because it determines the pattern of exclusions. This was first shown by Markovsky, Willer & Patton (1988), who demonstrated that changing the number of exchanges allocated to positions altered the power exercised in every relation in the network. More recently, Skvoretz and Willer (1993) showed similar consequences for a new array of

FIGURE 1: Four-Actor Line and Its Likelihood



networks. A real-world example will show why altering the number of exchanges has such a great impact on power. Auctions are a network exchange process. The seller has only a finite amount of time to sell any and all items at the best possible price. The finite period for the auction corresponds to a round of negotiation, that is, the period in which exchanges involving existing pools of resources must be completed. A resource pool might consist of a single item or several identical items, or there might be several resource pools containing a wide variety of items as in a real auction. Different items may appeal to some or all of a wide variety of bidders, which determines the pattern of relations in the exchange network.

Consider two simple auctions. In both we have one seller and two buyers. In the first auction, there is only one item, an antique lamp, of interest to both buyers. In the second auction, there are two such lamps. In the first auction, because there is only one lamp, the seller and each of the buyers can make only one exchange during the auction but one of the buyers will be excluded from exchange. As the bidding opens, each buyer must try to provide the seller with the more lucrative offer. Because each buyer wants to make the higher bid, however, the offers "ratchet" higher and higher and become increasingly

favorable to the seller. Eventually, one buyer backs down and the seller accepts a tidy profit.

In the second auction, each buyer (who wants only one lamp) still seeks exchange with the seller. But because there are two lamps, the seller now may exchange twice during the auction period — once with each buyer. The buyers do not need to outbid each other in order to obtain the lamp they desire, and so there is no structurally induced exclusion from exchange and no price ratcheting. Ironically, the combined prices for the two lamps may end up being less than what the seller could have obtained by placing only one up for auction. Varying the number of permitted exchanges emphasizes the importance of exclusion as the generator of structural power in networks, as well as the generality of the theory (Skvoretz & Willer 1991).

Despite the theory's generality, the structurally induced exchange likelihoods that it generates have been used to predict only the ordering of exchange outcomes across positions in weak power networks. We now turn to the problem of predicting exact exchange rates in weak power networks.

Profit Expectations

Network exchange theory depicts the generation of profit differentials in networks as an almost purely structural phenomenon. Profit differentials arise from differences in avoiding exclusion and from the sheer pattern of ties. The cognitions of actors play very little role in explanation. The strategy has been fruitful for two reasons. First, structural factors are often sufficient to predict accurately simple ordinal differences in earnings. Second, strong power networks have played an important developmental role in network exchange theory. In strong power networks, structural determinants are so powerful — as indicated by consistently extreme profit differentials — that actor cognitions can introduce only minor variation at best. But the study of weak power networks demands that more sources of variation be taken explicitly into account. In particular, we hold that more precise prediction requires that we extend network exchange theory to incorporate actors' profit expectations. We concentrate on possible sources of actors' expectations that might develop from initial network conditions and ongoing feedback that might result from them because our goal is to predict actor behaviors and exchange outcomes on the basis of initial conditions.

In exchange networks, initial conditions and ongoing feedback provide actors with information that they can use to estimate their potential profits, e.g., the maximum amounts they could hope for, the minimum outcomes they fear, and the profits that might reasonably be expected to obtain. To the extent that such profit expectations are affected by situational factors, negotiations will be modified and, in turn, exchange profits will be affected. The sensitivity of the negotiation process to contextual information should be especially evident in experimental settings. There, the simplicity of exchange conditions focuses attention on whatever minimal information is provided.

Our strategy is thus to employ a formal model that (1) accounts for the effects of profit expectations, (2) can be readily extended to accommodate situational factors that modify such expectations, and (3) may be integrated

seamlessly into existing network exchange theory. In line with the existing theory's emphasis on the importance of exclusion and excludability, we assume that a situational factor also modifies actors' profit expectations. It would be surprising if it did not. We have all been excluded from social exchange at some time in our lives whether it was not being invited to a party or having our application to a university rejected. These events certainly affect our cognitions. The following section incorporates the actors' experience of patterns of exclusion into our model. The second factor we will highlight in the section entitled Expectations and the Number of Direct Ties. Previous research (Marsden 1983) suggests the significance of the number of direct relations an actor has in the network. But more important, the number of direct relations is a highly salient and immediately apprehensible feature of the actor's environment even under conditions of highly restricted information.

EXPECTATIONS AND RESISTANCE

The resistance model (Heckathorn 1983; Willer 1981) predicts rates of exchange based on each actor's beliefs or expectations about his or her own best and worst possible outcomes. Specifically, it assumes that the point at which actors agree to exchange is determined by balancing two interests: (1) Actors aspire to obtain the greatest possible profit from exchange. This is their "best hope." (2) Actors seek to avoid the worst possible outcome. This is their "worst fear." To decide whether to agree to exchange, actors balance their desire for maximum profit against their fear of receiving no profit or the profit that results if no exchange occurs.

In dyadic exchange, the scope of the resistance model overlaps the Nash equilibrium (1950, 1953), and under certain conditions the predictions of the two are the same. However, the scope of the resistance model is broader, extending beyond the dyad. It has been successfully applied to a wide range of exchange networks (Brennan 1981; Willer 1987; Willer, Markovsky & Patton 1989). Its predictions have also been shown to hold in cross-national experimental research (Willer & Szmatka 1993).

We use the resistance model to formalize our claims about the effect of profit expectations on negotiations. It specifies how negotiators arrive at agreements through each actor's beliefs or expectations about his or her own best and worst possible outcomes. Implicitly, the model may be interpreted as generating profit expectations for negotiating actors at a particular point in time, and these expectations then determine whether actors accept or reject offers.

Let P_i represent i's profit from exchange, M_i is i's maximum expectation or best hope for profit from exchange, and C_i is i's worst fear or "conflict outcome."[4] Actor i's interest in gaining his or her maximum expectation is $M_i - P_i$ and in avoiding his or her worst fear is $P_i - C_i$. His or her resistance to a given exchange profit, R_i, is the ratio

$$R_i = \frac{M_i - P_i}{P_i - C_i}$$

Resistance is the ratio of $M_i - P_i$, the actor's interest in gaining a better outcome, to $P_i - C_i$, the actor's interest in avoiding disagreement. Because the ratio is

small for favorable settlements and large for unfavorable settlements, resistances of two actors in an exchange relation vary inversely for a given settlement. Network exchange theory asserts that agreements to exchange occur when actors' resistances are equal. Thus, compromise occurs when:

$$\frac{M_i - P_i}{P_i - C_i} = \frac{M_j - P_j}{P_j - C_j}$$

This is the *equiresistance* solution.[5] Knowing the number of resource units in the pool (P) such that $P = P_i + P_j$, we may algebraically solve for the values of P_i and P_j. More than a decision strategy, resistance is conceived as a potential limit of power use when actors use the best available strategies. Consequently, it holds promise of more general applicability than any particular decision strategy.[6]

To predict negotiation outcomes, M_i and C_i must be determined for each actor. In strong power structures such as A-B-A, we assume that each A's maximum expectation (M_A) is initially at or near P. However, given that B seeks only one exchange per round, M_A declines as A's are consistently excluded. M_A may begin at or near P, but this best hope will approach zero as exchanges continue to yield ever-declining profits. In contrast, because B has no rivals, M_B remains close to P. Over a series of rounds all profit gravitates to the central, B, actor (Willer & Markovsky 1993).

C_i is determined by a position's best alternative (Willer 1987). Strong power structures such as A-B-A are characterized by bidding wars between rival A's. Thus, when B negotiates with one A, C_B is the last offer from the other A. As the two A's bid, however, C_B increases toward P. Because A has no alternative, C_A stays at zero. The result over a series of exchange rounds (derivable from the equiresistance model) is that P_A approaches zero and P_B approaches P (Willer & Markovsky 1993).

In weak power structures, an equilibrium exchange rate is reached such that neither actor gains the maximum available profit or is forced to accept almost none. To use resistance to predict exchange rates in these structures, it is necessary to determine the value of actors' maximum expectations and conflict outcomes, M_i and C_i, at equilibrium.

In weak power structures, actors do not initially have a realistic basis for estimating their maximum expectations and conflict outcomes, M_i and C_i. As a result, their initial expectations may be either optimistic or pessimistic. However, all equiresistance solutions assume that actors have expectations and that over a series of exchanges they come to be more or less realistic. Thus, we assume that during the interaction process actors learn more realistic expectations. For example, when initial expectations are too optimistic, actors are excluded by others and eventually adjust their expectations downward. If expectations are initially too pessimistic, then actors always gain agreements and eventually adjust their expectations upward. As a result, expectations become increasingly realistic. This model of actors' responses to inclusion and exclusion conforms to the scope specifications for offer adjustments first described by Markovsky, Willer & Patton (1988). Here, however, we make the more specific suggestion that actors adjust their offers in response to changes in their profit expectations.

Below, we offer a two-part solution for the problem of predicting exchange rates in weak power networks. First we predict the equilibrium exchange rate. If actors adjust expectations as we assume they do, then expectations will come to correspond more closely to actors' likelihoods of being included in exchange. The result will be a fairly stable equilibrium exchange rate.

Second, we note that initial rates may not be like equilibrium rates. Because actors do not initially know their likelihood of being included in exchange, their expectations for maximum profit and their worst fears must have other bases. Initial expectations may or may not be realistic. We also offer a simple model for initial expectations from which actors move, as a consequence of interaction, toward equilibrium. These initial expectations likely have an enduring impact on exchange rates. In a final step, we complete our theory by combining the model of initial expectations with equilibrium exchange rate predictions. In effect, our predictions assume that actors' beliefs remain biased to some degree by initial expectations.

RESISTANCE AND THE LIKELIHOOD OF BEING INCLUDED

We approach the problem of specifying the value of conflict outcomes and maximum expectations in weak power networks by first identifying theoretical restrictions for C_i and M_i. Within these theoretical limits, we then assume that C_i and M_i are proportional to an actor's likelihood of being included in exchange. That is, an actor's expectations for profit, her or his worst fears and best hopes, depend on how often she or he expects to be included in profitable exchange. The assumption of simple proportionality between inclusion expectations and likelihood of being included results in a modified resistance equation that can be used to make exact predictions of exchange rates between actors in weak power networks.

The conflict expectation, C_i, depends on the actor's expectations regarding available exchange alternatives, as noted above. For example in the four-actor line network, A_1-B_1-B_2-A_2, if B_1 knows that A_1 will agree to an equal division of profit at 12:12, then B_1 will not accept 11 from B_2. However, as Yamagishi and Cook (1990) noted, actors are not always certain of their alternatives. Nonetheless, weak power limits the range of conflict outcomes: the lower limit is zero — the amount an excluded actor receives — and the upper limit is half the total resource pool, as we will next explain.

In all weak power networks, actors cannot consistently exclude others from exchange without themselves suffering losses.[7] Still assuming 24-unit resource pools, this can be illustrated using the four-actor line. Suppose that C_{B1} is greater than 12, an equal division of the profit pool. This means that B_1 would refuse offers of less than 13. That is, B_1 will refuse an equal division of profit and hold out for more. Because B_1 cannot consistently exclude B_2, however, B_2 will not be penalized for refusing to exchange with B_1 at this rate. As long as B_1 demands 13 from B_2, B_2 effects a temporary break in the network by exchanging with A_2 at no worse than 12:12. For B_1 to ever reestablish the possibility of exchanging with B_2 (and thus reestablish weak power over A_1), C_{B1} must be reduced to 12, an equal division of the profit pool, or lower. Therefore, it is generally true that the "conflict" or worst-fear outcome in weak power

structures is limited to the range from zero to half the size of the resource pool. Similarly, M_i is restricted to the range 12-24. M_i may be close to the total resource pool when exchange begins, but it cannot go below half the pool. Half the pool is always a competitive offer because no actor is ever consistently excluded.

At issue now is how to determine C_i and M_i from initial conditions within these theoretically determined ranges. We do so using l, the likelihood of being included, as derived from weak power calculations (Markovsky et al. 1993). Two assumptions integrate resistance with Network Exchange Theory. First,

Equiresistance Assumption: In weak power relations, actors' profits approach equiresistance solutions over a series of exchanges.

To the extent that actors use effective strategies to seek maximum profits, their profits should conform to the resistance predictions. For example, the behavior of more experienced actors or those with better training should conform more closely to resistance predictions than the behavior of less experienced or less well trained subjects.[8] The idea that resistance predicts a profit limit reached at equilibrium after a series of exchanges allows application of the theory to exchange situations in which actors have different amounts of information and training.

Second, we theoretically link inclusion probabilities to actors' conflict outcomes and best-hope outcomes in the resistance equation. We assume that an actor's perceived best-hope and conflict outcomes are proportional to that actor's likelihood of being included in exchange. For example, an actor who is consistently included and who makes a profit would resist offers that are lower than she or he is accustomed to receive. The fact that she or he is very likely to be included in exchange has increased her or his point of conflict. Conversely, a frequently excluded actor, accustomed to receiving no profit much of the time, would accept a low offer. The actor's low likelihood of exchange has reduced her or his point of conflict. The same argument can be made for actors' best hopes. Actors consistently included in exchange should have higher aspirations for profit than should actors consistently excluded from exchange.

Markovsky et al. (1993) demonstrated that likelihood of being included (l_i) ranks the power of positions in weak power networks. On this evidence, we assume that l_i will successfully rank power positions even where power differences are very small. Further, we assume that larger differences in l_i identify larger differences in power between positions. That is, we assume that weak power is proportional to a position's l_i. If as we suggest, this occurs because likelihood of being included acts on points of conflict (C_i) and best hopes (M_i), then setting C_i and M_i proportional to l_i should provide a good indicator of an actor's power.

The following resistance-likelihood assumption expresses the idea that C_i and M_i are proportional to l_i within their respective ranges. Our analysis demonstrated that C_i is limited to a range between zero and half the resource pool. Similarly, M_i is limited to a range from half the resource pool to the entire pool. This assumption predicts that the difference in profits for high-power and low-power actors in a weak power relation depends upon their likelihoods of being included in exchange.

Resistance-Likelihood Assumption: The higher an actor's likelihood of being included in exchange, (1) the higher the actor's perceived conflict outcome, C_i; and (2) the higher the actor's maximum profit expectation, M_i. Formally,

$$C_i = \frac{P}{2} l_i \qquad (1)$$

$$M_i = \frac{P}{2}(l_i + 1) \qquad (2)$$

In words, the perceived worst-case exchange outcome (C_i) is a fraction of half the pool, and that fraction is larger for higher likelihoods of being included (l_i), and smaller for lower l_i. As explained above, C_i is limited to at most half the resource pool in weak power situations. Equation (1) expresses the assumption that C_i is proportional to l_i and ranges between zero and half the resource pool.[9] Similarly, an actor's maximum expectation for profit (M_i) is half the pool plus a fraction of half the pool. We also showed that M_i is restricted to be at least half the resource pool but not more than the total pool, P, in weak power situations. Equation (2) expresses the assumption that M_i is proportional to l_i on that range. In weak power situations at equilibrium, it follows from equations 1 and 2 that M_i is a direct function of C_i, i.e., $M_i = C_i + P/2$. This feature pays considerable dividends in simplifying calculations and serves as a plausible assumption about perceived best- and worst-case outcomes.

The resistance model, resistance-likelihood assumption, and a little algebra yield the following prediction:[10]

$$P_i = \frac{(P + C_i - C_j)}{2}$$

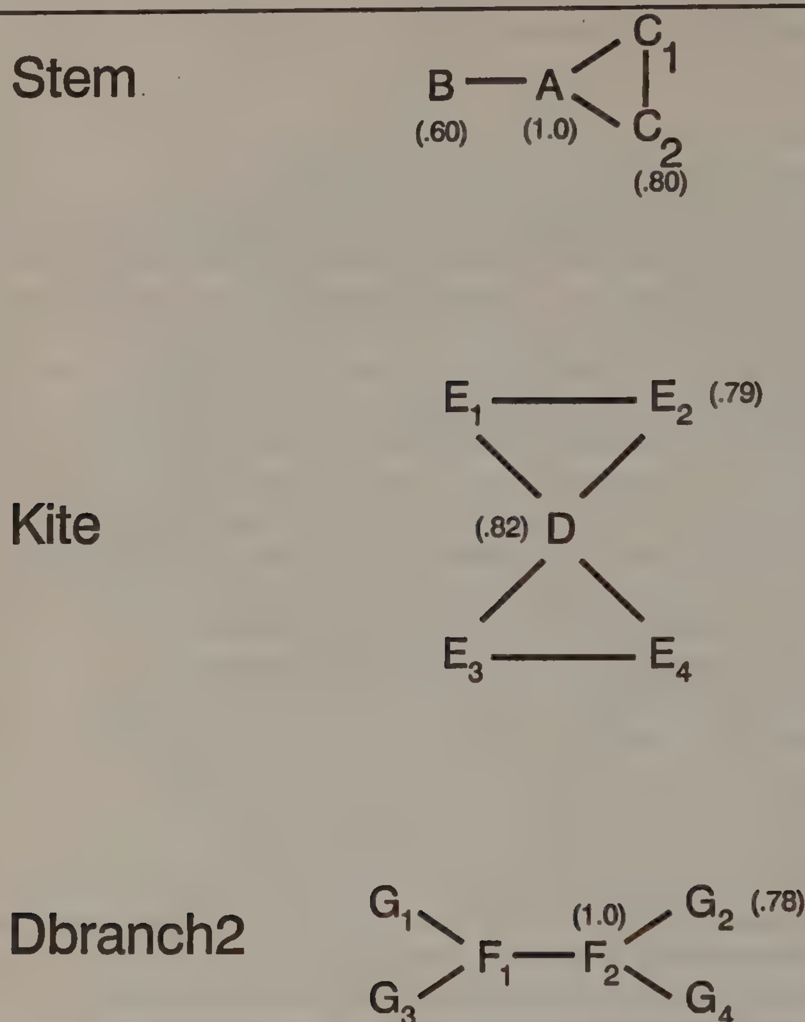
$$P_j = P - P_i.$$

In the Stem network (Figure 2), for example, likelihoods of being included for positions A and B are $l_A = 1$, $l_B = .6$. Assuming a typical 24-point resource pool, P, we can calculate profit distributions for the A-B relation. First, by the resistance-likelihood assumption, $C_A = (24/2) \bullet 1 = 12$, and $C_B = (24/2) \bullet .6 = 7.2$. Next, profits are calculated to be $P_A = (P + C_A - C_B)/2 = 14.4$, and $P_B = P - P_A = 9.6$. Profits for any position in any weak power network can be predicted by this method if the network structure and total value of each profit pool are known. Likelihood of being included indicates the structural power advantage of a network position. By balancing two competing motives — the desire to increase profit and the need to reach agreement and avoid exclusion — actors reach an equilibrium level of profit that is proportional to their relative likelihood of being included.

EXPECTATIONS AND THE NUMBER OF DIRECT TIES

In addition to the factors that we have previously related to profit expectations, there is good reason to assume that the number of an actor's direct relations in the network may also play an important role. In the parlance of network analysis, this refers to the actor's degree. Marsden (1983) employed a similar idea in his theory of power in exchange networks. Where t_i is the number of actor *i*'s direct network ties, he defined $\log(t_i/t_j)$ as one of several factors affecting *i*'s "price-making" behavior in exchanges with *j*. Although some of his

FIGURE 2: Three Weak Power Networks and Likelihoods of Inclusion



model's predictions diverge from experimental test results, the notion that degree biases actors' price negotiations in weak power situations has not been tested directly and may still be sound. Further justification is found in the judgment heuristics literature (e.g., Kahneman, Slovic & Tversky 1982). In a wide variety of judgment contexts, informational anchors have been shown to bias judgments of such properties as magnitude, numerosity, value, weight, color, loudness, pitch, etc. For example, a contrast anchor effect occurs when yesterday's 95 degree temperature (the anchor) makes today's 78 degrees seem cool. Today's judged temperature is biased away from yesterday's. The assimilation anchor effect is often found in negotiation settings where an initial offer (the anchor) may be blatantly unrealistic, but subsequent offers and counteroffers are still pulled toward that initial offer. (For more detailed examples and applications see Helson & Kozaki 1968 and Kahneman, Slovic & Tversky 1982.)

Assuming that human actors cannot fully evaluate the ramifications of their location in a network structure — especially when lacking systemwide information — it is reasonable to presume that information of a more localized

nature becomes especially salient. The number of one's direct ties is just such a piece of information. An actor with more direct network relations will probably expect to have more successful negotiations than an actor with fewer direct relations. It seems plausible that an actor with many potential exchange partners would expect a better chance of being included in exchange than would an actor with only one or very few exchange partners. Of course, network exchange theory shows that this expectation is not necessarily justified. The extent to which having alternative partners can benefit an actor depends on broader network patterns, e.g., the alternative relations of each of one's alternative relations. Nevertheless, an actor's degree is a highly salient piece of information in network exchange contexts and should thus bias profit expectations via an assimilation effect.[11] This idea is captured in the following:

Degree Assumption: The higher an actor's degree, the higher the actor's expected profit.

An actor with higher profit expectations is assumed to adopt a tougher bargaining stance, e.g., to make lower offers to others, and to have higher thresholds of acceptability for incoming offers. If negotiating actors have equally high degrees, however, degree would not provide special advantages to either. Therefore, our index of relative degree (d_{ij}) for actor i in the i-j relation must actually be based on the relative number of ties (t) for each actor. This is accomplished in the formula

$$d_{ij} = \frac{t_i}{(t_i + t_j)}.$$

This specification standardizes the index to a 0-1 scale, a useful property when we combine d with other components of the theory. As a structural measure, d_{ij} does not depend on actors' knowing one another's degree. It captures what might be called the expectation advantage of one actor relative to another — a condition that will then manifest itself in the dynamics and outcomes of the negotiation process.

RESISTANCE AND DEGREE

Degree is assumed to bias profit expectations. Therefore, in the model, we incorporate the relative degree index as a biasing factor for best-hope and worst-fear outcomes. Given that we have already defined M (the maximum hoped-for profit) to be a function of C (the conflict or worst-fear outcome) in weak power networks, we need to show only how relative degree affects the latter. We assume that, in the same manner as the likelihood of being included, the higher the degree, the greater the inflation of the actor's worst-fear outcome:

Resistance-Degree Assumption: The higher an actor's relative degree, the higher the actor's perceived conflict outcome.

Combining this assumption with the resistance-likelihood assumption yields

$$C_{ij} = \frac{P}{2} l_i d_{ij}$$

We now subscript C by both i and j, because the inclusion of the biasing factor, d_{ij}, in the equation implies that i's expected conflict outcome may be different for each actor with whom i negotiates.[12] Again using the Stem network as an

example, and using the earlier formulas for P_i and P_j with a 24-point resource pool, $d_{AB} = 3 / (3+1) = 3/4$. Substituting the values for variables in the equation, $C_{AB} = 24 / 2 \cdot 1 \cdot 3 / 4 = 9$; $C_{BA} = 24 / 2 \cdot .6 \cdot 1/4 = 1.8$. Then we can solve for the prediction that incorporates both resistance and relative degree into the GPI model, $P_A = (24 + 9 - 1.8) / 2 = 15.6$, and $P_B = 8.4$. We label this elaborated model GPI-RD.

Higher relative degree is thus assumed to bias the effects of the likelihood of being included. However, because advantages in relative degree are based only on actors' expectations and not on actual structural advantages, there is a potential cost to actors who try to exploit degree advantages. Though an actor with more potential exchange partners may be a tougher negotiator and receive more resources from completed exchanges, such exchanges may be less frequent than for actors of lower degree. This is because higher-degree actors are prone to tougher negotiation than is warranted by their actual structural positions. The result would be higher profit when exchange occurs, but a higher likelihood of being excluded from exchanges. In addition, actors with fewer potential exchange partners still seek more favorable alternative agreements whenever possible. In networks where all actors can be excluded — l_i less than 1.0 for all actors — a situation could arise in which an advantaged actor is excluded from exchange so frequently that she or he can actually acquire fewer resources than the disadvantaged actor over a series of exchanges. Markovsky et al. (1993) report this phenomenon in the "Kite" network (Figure 2). Subjects in the D position have an advantage over those in E positions both in likelihood of being included, .82 to .79, and relative degree, 4/6 to 2/6. For experienced subjects, despite the very small advantage in likelihood of being included, D position subjects averaged a 14:10 profit point advantage in exchanges with E partners. However for D these victories were Pyrrhic. Ds were excluded — and earned no profit — on 41% of rounds, while Es were excluded on only 15% of rounds.[13] Es preferred to exchange with each other rather than the more aggressive D. It seems strange that a high-power actor can actually earn less overall than a low-power partner. Incorporating degree into the theory explains this result — a result that previously had been considered anomalous. Though frequency of exchange can also be predicted using likelihood of being included and degree (Skvoretz & Lovaglia n.d.), here we focus on testing the model's predictions for exchange profits.

Method

We tested the model's predictions using experimental data from four networks. Subjects in the test setting had full information on the network structure and on all other actors' exchange outcomes. We also replicated the test on one of these networks using a restricted information setting where each subject knew only his or her own dealings with potential exchange partners and his or her own profits from exchanges.

EXPERIMENT 1: "FULL INFORMATION" NETWORKS

Skvoretz and Willer (1991) described in detail the experimental setting used for these tests. Custom software ("ExNet") was used to configure networked PCs into "virtual" exchange networks. ExNet can establish networks of any shape and size, limited only by the number of PCs. Subjects in experiments know the network structures and their positions within them. In an initial session, assistants explain how to make offers and counteroffers, what it means to divide the 24-point resource pool, the dollar value of profit units, and that exclusion from exchange yields no points for that round. A practice session familiarizes subjects with the operation of the system. Subjects then return at a later date to participate in the actual research. In the experiments, each subject rotates through all network positions, negotiating for a total of four rounds at each position. The computer records the timing and content of all communications.

We investigated four experimental structures of theoretical import (Figure 1a and Figure 2). The Double Branch 2 is a simple weak power network that allows two positions multiple exchanges. It was converted from a strong to a weak power structure via a two-exchange rule: The central Fs could exchange up to twice per round. Actors are only allowed one exchange per round in the other structures. These networks also have interesting theoretical properties that warranted our attention: The four-line is the simplest weak power network; the Stem and Kite sparked a debate between competing research programs over the validity of the GPI (Markovsky, Willer & Patton 1990; Yamagishi & Cook 1990); and in the Kite, no position is guaranteed inclusion.

Five alternative theories are capable of generating ratio-scale profit predictions for positions in weak power networks. Most of these were presented in a special issue of *Social Networks* (Bienenstock & Bonacich 1992; Cook & Yamagishi 1992; Friedkin 1992; Skvoretz & Fararo 1992). Bienenstock and Bonacich's core theory takes a game-theoretic approach. Cook and Yamagishi's equidependence theory extends the power-dependence program originated by Emerson (1962). Friedkin's expected value theory developed out of his work on network analysis in general. Skvoretz and Fararo (1992) apply Coleman's (1973, 1990) rational exchange theory to these exchange structures. In addition, Skvoretz and Willer (1993) present exchange resistance theory, a model that incorporates resistance into the GPI but does not include degree. These five theories are briefly described below. Except for Coleman's rational exchange model, Skvoretz and Willer (1993) provide details for using each to calculate predicted exchange outcomes.

CORE THEORY

Core theory (Bienenstock & Bonacich 1992, 1993) models network exchange in terms of cooperative game theory.[14] Three rationality criteria establish the "core" of an exchange network. First, agreements are individually rational when each actor's profit is equal to or greater than the profit that could be earned by not exchanging. That is, actors are assumed to exchange only when they receive at least as much profit from agreement as they do from being excluded from exchange. Second, agreements are rational for the coalition of exchange partners

when the sum of the profit of both actors is at least as much as could be obtained if they exchanged with other partners. Third, group (or network) rationality obtains when the total profit of all positions of the network is at least as large as the total profit available from some other pattern of exchange agreements.

The core of an exchange network usually narrows the range of preferable exchange rates but does not necessarily predict a single ratio-scale exchange outcome. To make predictions when this occurs, we follow Skvoretz and Fararo (1992) in assuming that each core outcome is equally likely and then average the payoffs to various positions. In some cases, networks contain no core at all, which precludes a prediction.

RATIONAL EXCHANGE THEORY

Coleman's (1973, 1990) rational exchange model is not easily applied to our exchange networks because it operates under scope conditions that differ from those of other network exchange theories. It assumes, for instance, that every actor may exchange with any other actor in a network. Marsden's (1983) model solves the problem by adding network restrictions and a variety of additional assumptions. However, he noted that some predictions ran contrary to data previously published. Coleman partially solved the problem by assuming that there are transaction costs between actors. When transaction costs are high, they effectively prohibit exchange from occurring, thus setting the stage for structural power to emerge. As it stands, however, Coleman's conception of power is not relational. Power manifests in an actor's resource holdings rather than in her or his relative ability to extract resources through exchanges. Also, it does not address the situation where one actor's exchange is contingent on whether another actor exchanges. Skvoretz and Fararo (1992) have modified and added assumptions to Coleman's theory to make it applicable in the kind of exchange networks discussed here. Predictions for the Coleman model are based on their analysis. A technical description of the method and a computer program that calculates predictions are available from the second-named author on request.

EQUIDEPENDENCE THEORY

Equidependence theory (Cook & Yamagishi 1992) assumes that actors compare how much they will receive in exchange with a potential partner against how much they could get in exchange with some other partner. The difference between what an actor can obtain from this exchange relation and that of an alternative relation is deemed to be the dependence of the actor on the potential partner. This comparison process goes on simultaneously with all an actor's direct ties. Actors are assumed to exchange at a point where their dependence on the relation is equal to the dependence of their potential partner. In other words, exchange occurs when actors are equidependent, and each actor can get no more profit by some alternative exchange. An actor's reward from exchange is given by the equation $R_{ij} = (P_{ij} + A_{ij} - A_{ji})/2$, where R_{ij} is the profit that actor i obtains in exchange with partner j; P_{ij} is the pool size, and A_{ij} is the best alternative available to i.

Cook and Yamagishi use the example of two actors, *i* and *j*, negotiating over a 24 point resource pool. Actor *i* has another partner who offers *i* 10 points, while *j* has no other partner. If *i* and *j* were to divide the pool at 13 for *i* and 11 for *j*, actor *i* gets 3 points more than his or her best alternative (10), but *j* gets 11 points more than his or her alternative (zero). Thus equidependence between *i* and *j* has not been reached. Negotiation is assumed to continue until *i* gets 17 points and *j* gets 7 points. Here, equidependence has been attained because both *i* and *j* get 7 more points from exchange with each other than they would outside the *i*-*j* relation. Actor *i*'s power is defined as the maximum profit she or he can obtain from any partner.

EXPECTED VALUE THEORY

Friedkin's (1992) expected value theory first identifies all subnetworks that can result from various patterns of exchanges. Expected values are predictions about a structure's outcomes determined by weighting the value of a predicted outcome by the probability of its occurrence. For example, in the four-actor line network, A_1-B_1-B_2-A_2, there are two possible exchange patterns. Either each B exchanges with its related A, or the two Bs exchange with each other. To make predictions from initial conditions, Friedkin assumes that either pattern is equally likely to occur. Actor *i* is dependent on actor *j* if failure to exchange with actor *j* results in *i*'s exclusion from exchange. Dependency is an actor's likelihood of being excluded, calculated over all possible exchange outcomes. An offer-making function translates a particular degree of dependency into an offer to a potential exchange partner. Predicted earnings from exchange are a function of reciprocal offers modified by compromises when offers are inconsistent.

EXCHANGE RESISTANCE THEORY

Skvoretz and Willer (1993) use the likelihood of being included and the resistance model to make "baseline" predictions for exchange in both strong and weak power structures. Their goal is a simple formula that can be used in a single step to yield predictions in all exchange networks. We give their formula for predicting the profit of actor *i* using the notation for our own resistance-likelihood assumption:

$$\frac{\ln(M_i - P_i)}{\ln(P_i)} = \frac{l_j}{l_i}$$

They assume that conflict points and maximum expectations for profit for all actors remain constant. The conflict point for all actors is assumed to be zero, and their maximum expectation for profit is assumed to be the entire profit pool. A power function is then applied in which the difference between the maximum expectation for profit and what an actor would receive from an offer is raised to the power of that actor's likelihood of being included in exchange. The equiresistance equation can then be reduced to the above equation using natural logarithms.

All five theories make ratio-scale predictions for at least some of the network relations we examined. Below we compare our predictions to those of the five alternative theories and to experimental results.

Results

Four groups of subjects participated in Stem and Kite experiments, and five groups in the four-line and Double Branch 2. All were university students who signed up to participate in paid experiments. In Table 1, the column headed GPI-RD shows the predictions for our new model that integrates GPI, resistance, and degree. The column headed GPI-R shows the predictions for our resistance model without the biasing effects of degree. Also shown are the predictions from five alternative models and the observed means by network relation. Because we assume that profits approach predicted equilibria over a series of negotiations, we use data from the final experimental periods.[15]

Observed profits conform well to GPI-RD predictions. The largest discrepancy between a predicted and an observed value is less than one profit unit. One-sample t tests determined the probability that the differences between predictions and observed means were due to chance. No GPI-RD prediction differed significantly from its corresponding observed mean at or below the .40 probability level. The smallest probability that a prediction did not differ from the observed value was .47 for the Kite network. Two predictions from Coleman's (1973, 1990) rational exchange model, while not as close, were better than those of other alternatives. The probability that rational exchange predictions did not differ from observed values was .13 for the four-line and .11 for the Stem. In contrast, significant differences were found between observed means and the predictions of other alternative theories. For the Kite network, Skvoretz and Willer's (1993) exchange resistance model, GPI-RD, Cook and Yamagishi's (1992) equidependence model, and Friedkin's (1992) expected value model all make acceptably close predictions. However, both the equidependence and expected value models predict no difference in power between D and E actors in the Kite — a difference that did occur in an empirical test and was statistically significant (Markovsky et al. 1993).

Establishing a GPI-RD prediction for the Double Branch 2 network requires some interpretation. Calculating degree as for a one-exchange network, Fs have three direct ties and Gs have one. The GPI-RD model then yields predicted profits for F of 15.33, about 1 profit point away from the observed value. A one-sample t test also finds this difference significant: $t(63) = 2.29$, $p = .03$. However, degree can be calculated differently when two exchanges are allowed. Fs exchange twice per round while Gs exchange only once. At the beginning of a round, F has three potential exchange partners. If F's first exchange in a round is with a G, then there are two actors left with whom to attempt a second exchange. If Fs first exchange with each other, then they have three actors left with whom to attempt a second exchange. Fs then have either five or six direct ties while Gs have only one. If F's first exchange is with a G on two-thirds of the rounds (i.e., F is indifferent between the other F and its two Gs), then Fs effectively have 5.33 direct ties. This produces a GPI-RD prediction for F in

TABLE 1: Goodness of Fit[a] for Predicted and Observed Profits in Exchange Networks

Structure, Relation	Core	Rational Exchange	Equi-depend.	Expected Value	Exchange Resistance	GPI-R	GPI-RD	Observed Means
4-Line								
B-A[b]	16.0	15.0**	16.0	21.0	16.0	13.5	14.5****	14.4
t (29)	4.27	1.54	4.27	13.01	4.27	-2.54	0.18	
Stem[c]								
A-B	20.1	17.2**	18.0	22.0	18.3	14.4*	15.6****	15.9
t(13)	5.46	1.72	2.76	7.91	3.15	-1.88	-0.33	
Kite

(Column group heading: Models and Predictions)

[a] One-sample *t* tests were used to estimate the probability of no difference between prediction and observation. Larger *p* values suggest an increased likelihood that prediction and observation are identical. Degrees of freedom are in parentheses.

[b] Predictions are for profits of the first position listed in a relation; here, for example, actor B in B-A.

[c] The A-C relation is also of interest in this network. However, during the last period of the experiment, A exchanged with C only twice, both times at 14-10. This precludes meaningful comparison. With that caveat, we report only for completeness that the GPI-RD prediction of 13.7 for this relation was closest among the models, though the equidependence and rational exchange models were also close.

* $p > .05$ ** $p > .10$ *** $p > .20$ **** $p > .40$

exchange with G of 16.31. A *t* test finds no difference between this value and the observed mean, 16.36, $t(63) = -.14$, $p = .89$. While this is the closest prediction of any model, Table 1 shows that the Bienenstock and Bonacich (1992, 1993) core and Cook and Yamagishi (1992) equidependence models also make acceptable predictions for the Double Branch 2.

In sum, the GPI model incorporating resistance and degree formulations produced very accurate predictions for exchange outcomes. These predictions were superior to alternative models in their goodness of fit to experimental data: Only GPI-RD makes acceptably close predictions ($p > .40$ of no difference between predicted and observed values) for all four experimental networks.

EXPERIMENT 2: RESTRICTED-INFORMATION NETWORKS

There is a theoretical distinction between full- and restricted-information settings used for network exchange experiments. Full-information settings more closely model rational, forward-looking actors who use whatever information is available. Restricted-information settings conform better to backward-looking actors who adjust their response only on the basis of their experience in the situation. Our model requires that, minimally, three information conditions must be satisfied for negotiated social exchanges to occur:[16] (1) An actor in the network must be informed of, and have access to, other actors with whom it is possible to exchange. We assume that actors negotiate separately with each potential partner and are thus aware of each partner as a distinct person or organizational unit. Implicitly, then, actors also know the number of others with whom it is possible to exchange. (2) The actor must be informed of whether an exchange has been completed with each potential partner. (3) The actor must be informed of the magnitude of her or his profits from exchanges. In order to evaluate an offer, it must be at least ordinally scalable. This requires information on the offer's relative magnitude. In a typical experiment, this takes the form of an agreement between two partners to allocate a pool of resources at the conclusion of a given negotiation round. Implicitly, if actors know the magnitude of the offer upon which agreement was reached, then they also know the magnitude of their own shares of subsequent resource allocations stemming from the agreement. Knowledge of others' profits is not essential. Therefore, to examine the empirical scope of our model, we examine data from experiments in a new, restricted-information setting that differs in several ways from the full-information setting described above. The new setting restricts information to the minimum necessary for the operation of factors deemed important in the model.

As our theory evolves, refinements in its predictions demand that we study increasingly subtle network exchange phenomena. Consequently, our experimental setting must be made increasingly sensitive to predicted phenomena, and it must exert more stringent controls over potentially extraneous factors such as equity concerns. We have attempted to accomplish this by creating a new experimental setting that spreads the negotiation process across a larger number of rounds and limits information to the minimum necessary for negotiation and exchange. Each subject has information only on his or her own (1) negotiations and exchanges, (2) potential profit vis-à-vis particular offers received from others, and (3) realized profit when an exchange occurs. In addition, subjects negotiate for many more rounds because a subject's intra-round negotiations with a partner are simplified to a choice of three options: increase or decrease the previous offer by one "profit point" or do not change the previous offer. Cook et al. (1983) limit information in a similar fashion but allow subjects to select their offers from a wide range of possibilities on each round. The new setting then makes possible tests of our theory under information conditions similar to those of earlier restricted-information exchange experiments.

Custom software was used to configure networked PCs.[17] Subjects were isolated in separate rooms and knew only the coded designations for their own

potential exchange partners. They were informed that the shape of the full network would not be revealed and that their potential partners might have other potential partners of their own. An interactive tutorial guided subjects through the mechanics of conducting negotiations via the computerized system. On each round, subjects sent messages to a central computer telling it the lowest amount of profit they were willing to accept from each potential partner. If an agreement was reached, the subject was informed of this fact but did not know the amount of profit received by the partner; only her or his own profit was reported. Subjects completed a total of 60 rounds at the same network position. Each relation contained 30 profit points at the outset of each round, although subjects did not know the pool size. At the outset of negotiations, each partner could receive 15 points from an agreement, which was awarded as a 15-cent "bonus" for reaching an agreement. Subjects could raise or lower the amount they were willing to accept from each partner by 1 point, or leave the amount unchanged. Each 1-point change resulted in a 1-cent change in the amount of bonus for agreement. The computer declared an agreement when the sum of the profits for which two potential exchange partners were willing to settle did not exceed 30 points. If the sum was less than 30 points, the computer split the excess and awarded half to each subject in addition to the amount on which she or he had settled.

Because subjects made offers to all potential partners on each round, some could reach provisional agreements with more than one partner. Due to the fact that subjects were allowed only one agreement on each round, the central computer used the following algorithm to prioritize agreements: (1) Assign zero profit to subjects who do not reach any provisional agreement. (2) For those who remain, declare agreements for pairs of subjects whose best deals are with each other. (3) Select a subject randomly from those remaining and award her or his best deal. (4) Repeat the random selection until no more deals are possible.

This restricted-information setting differs from the full-information setting in several important ways.[18] Nevertheless, the settings are identical in several respects crucial to our model. First, in both settings the number of direct relations a subject has to others is immediately apparent and obvious. Therefore, degree can influence profit expectations. Second, in both settings, actors can over time get a sense of the range of acceptable terms through experiencing rounds in which they are excluded from exchange and rounds in which they are included. (This is true in the restricted-information setting even if some inclusions have a chance element because of computer intervention when multiple provisional exchanges could be made.) Therefore, excludability can influence expectations. On the basis of these essential similarities, we make the same predictions for profit differentials by position at equilibrium in the new restricted-information setting. That is, exchange rates in the last rounds of an experiment should be comparable across settings.[19]

RESULTS

Eleven groups participated in the Stem network. We treated the last ten agreements in a session for each relation as an indicator of its equilibrium exchange rate. This provides sufficient cases for a stringent statistical test and roughly corresponds to our use of last-period results in the full-information experiments. For the A-B relation, the last ten agreements varied by no more than a few points in all groups, allowing us to conclude that equilibrium had been reached. The maximum range over which agreements varied was 4 (M = 2.0; Std. dev. = 1.05).[20] In exchanges with B, the subject in the A position achieved mean profit of 20.13 (std. dev. = 4.29) out of a pool of 30 points, compared to the GPI-RD predicted level of 19.5. A one-sample t test found no difference between prediction and observation, $t(10) = -.49$, $p = .64$. Profit of 20.13 on a 30-point scale is equivalent to 16.10 on a 24-point scale, and thus very close to the 15.86 observed in the full-information experiment.

In previously reported experiments using the Stem network (Cook, Donnelly & Yamagishi 1992; Markovsky et al. 1993), A-C exchanges were infrequent. We had hoped that with 60 rounds in the new setting, we could establish an equilibrium value for this relation. This was not the case. A-C exchanges were still infrequent, especially during the final 30 rounds of a session. Two groups had no A-C exchanges during the last 30 rounds, and only four groups had ten or more. With such limited data, we lack confidence that equilibrium was reached. However, we attempted to test our prediction for A in the A-C relation by taking the overall mean for all A-C exchanges that occurred in the last half of a session (M = 17.46, Std. dev. = 3.77). GPI-RD predicts A will receive 17.10 profit units at equilibrium, a difference of less than half a profit unit from the observed mean. A t test found no difference between predicted and observed values, $t(82) = -.88$, $p = .38$. While this result does support the GPI-RD model, the variability in frequency of exchange argues against giving it much weight.

A significant difference was found in the C_1-C_2 relation. As with the A-B relation, we were able to use C_1's mean profit for the last ten exchanges for each group as an indicator of the equilibrium exchange rate in C_1-C_2 (M = 18.18, Std. dev. = 4.31). This difference in profit between isomorphic network positions is puzzling; all models predict an equal, 15:15, division of profit. Comparing this predicted value to the observed mean, we find that $t(10) = -2.45$, $p = .03$. The anomalous finding may be a chance occurrence, or an artifact of the experimental setting: The program treats C_1 and C_2 identically, with the one exception being that C_1 appears above C_2 as a potential partner on A's video screen. Possibly because of simple ordering, A may pay more attention to C_1 than to C_2, thereby affecting C_1's negotiations with C_2 in C_1's favor. While this might not affect the A-C or A-B equilibrium values (and thus show how robust GPI-RD predictions are for these relations), it could affect the C_1 - C_2 value. For the present, we regard this finding as a spur to additional research rather than as a disconfirmation of GPI-RD, since the finding is completely unanticipated by any alternative model.

To summarize, we replicated our test of the GPI-RD model using the Stem network in an information-restricted exchange situation. The key hypotheses were again supported.

Discussion and Conclusions

We developed a theory to explain how actors in social exchange networks reach agreements on divisions of resources. The model incorporates previous ideas about the effects that network structure has on the power of individual positions, specifically the graph-theoretical power index of network exchange theory and its weak power extension (Markovsky, Willer & Patton 1998; Markovsky et al. 1993). To this model we added theoretical ideas borrowed from several areas of sociology.

From elementary theory's concept of resistance, we borrowed the idea that actors balance two competing interests to reach agreement in exchange: (1) their "best hope" for maximum profit and (2) their "worst fear" of being excluded from exchange entirely. We combined this with an idea from network exchange theory: Likelihood of being included in exchange ranks the power of network actors. This resulted in a new assumption: Actors' best hopes and worst fears are proportional to their likelihood of being included in exchange. Actors who are frequently excluded from exchanges (and profit) are likely to lower both their maximum and minimum aspirations for profit. Conversely, actors frequently included in exchanges become accustomed to receiving profit and raise their expectations accordingly. Integrating these previous theoretical strands yielded a model that generates ratio-scale predictions for the outcomes of negotiating actors in exchange networks.

The fact that actors adjust their expectations through negotiation implies that structural power differences emerge over time. In strong power networks identified by network exchange theory, these differences never reach an equilibrium point short of the point of extreme differentiation. They continue until powerful actors receive all (or nearly all) available resources from exchange with less powerful actors. In weak power structures, an equilibrium point is reached well short of maximum differentiation. It is this equilibrium point that we attempt to predict theoretically and measure experimentally.

We felt that the equilibrium point eventually reached will likely be affected by actors' initial expectations formed on the basis of prominent features of their structural context. From network analysis we borrowed the idea that an actor's degree, the number of her or his direct ties to other actors, would influence her or his initial expectations for success in exchange. That is, actors with more direct ties would be biased toward resisting exchange offers that they would otherwise accept. We included degree as a biasing factor in predicting the equilibrium exchange point that experimental subjects would eventually reach. Results of an experimental test in a setting specifically designed to measure the equilibrium point suggest that our theoretical integration was successful. This brings up potential avenues for future research. The theory suggests that actors' expectations have significant effects on resource distribution only in weak power networks. What effects, if any, do expectations have in strong power

networks? Also, certain expectations about the social structure were shown to have important effects in weak power networks. Do other kinds of cognition have important effects? And under what conditions are cognitions likely to be more or less important?

Our extension of network exchange theory provides a number of advantages over earlier versions and current alternatives. By highlighting the ways that actors' profit expectations interact with structural properties of their locations in the network, it generates predictions for all positions in weak power networks on a ratio rather than an ordinal level of measurement. Moreover, these predictions are more accurate than those of alternative theories, and the theory generalizes across experimental designs. Our predictions closely approximate experimental results from the full-information experiments of Skvoretz and Willer (1991, 1993), the restricted-information experiments of Cook, Donnelly & Yamagishi (1992), and the results reported here for equilibrium rates in both full and restricted settings. In addition, results reported by Bienenstock and Bonacich (1993) for two weak power networks, the four-actor line and Kite, are extremely close to our predictions. Their experimental setting has features quite different from either the Skvoretz and Willer or Cook, Donnelly & Yamagishi designs. This remarkable convergence of experimental results in different settings demonstrates both the increased precision of the theory and its enhanced generality.

The empirical results also clearly suggest that equity concerns are not inextricably woven into social exchange network settings. This is not to say that equity effects are unimportant, but rather that equity is a distinct process that may or may not be activated in a given social context and that depends upon whether certain conditions are satisfied (Markovsky 1985). In developing our restricted-information setting, we struggled with the powerful effects of subjects' equity concerns when they felt they were receiving less than a partner who in other ways was their status equal. In some cases, subjects would refuse to exchange in as many as 50 out of 60 rounds because another subject would receive more profit than they would. That is, subjects would refuse five or six dollars in pay to avoid receiving a few pennies less than their partner in exchange. This study demonstrates that once equity concerns are controlled, different experimental settings produce comparable structural effects on resource distributions resulting from exchange. Structural positions have an effect on power independent of equity concerns. An interesting area for further inquiry is exactly how equity effects combine with the effect of structural position under different conditions to produce power and profit differences in social exchange networks.

Let us note that the equation for actor profit, P_i, converges with part of Cook and Yamagishi's (1992) theory — their equation $R_{ij} = (P_{ij} + A_{ij} - A_{ji})/2$. In this model, R_{ij} is the profit that actor i obtains in exchange with partner j and corresponds to our P_i; P_{ij} is the pool size and corresponds to P; A_{ij} is the best alternative available to i, which corresponds to C_{ij}, i's expected conflict outcome. That is, i's best alternative is the least amount of profit i expects if exchange with j does not occur. A_{ji} is j's best alternative, i.e., C_{ji}. Despite these similarities, however, our model diverges from Cook and Yamagishi's in significant ways. Unlike A_{ij}, which refers to the objective profit under "conflict," C_{ij} is assumed

to be a subjective assessment or expectation of long-range profit from failure to reach agreement. We believe that one reason for our model's predictive success stems from this incorporation of the actor's point of view. This allows the new model to generate contrasting predictions that are here shown to be significantly more accurate than alternatives.

Although the predictions that we derived are accurate for the networks tested, these findings tell us only that the model is developing in potentially fruitful directions. Establishing its broader generality will require continued testing in a wider variety of networks. Further enhancements will be required to allow predictions with theoretical restrictions further relaxed. Of course, these have been our goals all along: to generate increasingly precise and accurate predictions for network exchange outcomes under increasingly robust conditions. With the theoretical and empirical developments reported above, we have worked toward achieving these goals.

APPENDIX: Network Exchange Theory

Key Terms

p = power	h = length of the longest nonintersecting path
d = domain	m_{idk} = number of i's nonintersecting paths of length k in domain d.
i, j = network positions	e = maximum exchanges per round

A network path is a series of connected positions, e.g., A-B-C-D. Two paths stemming from a given position i are nonintersecting only if i is the only position common to both. Thus, relative to the A position, A-B-C-D and A-B-E-F are intersecting paths (at B), but neither intersects with A-G-H.

Domains are network substructures. When $e > 1$, a position can have different power indices within different domains (see Markovsky, Willer & Patton 1988). The following criterion determines whether i and j are in the same domain. First, define an $e+$ position as one having more than e relations. Then, given the set V of all positions on a path (i.e., a series of linked positions) between i and j, i and j are in the same domain only if there exists a path such that either V = {Ø}, or all positions in V are $e+$ positions.

SCOPE CONDITIONS

The theory is deemed applicable when the following conditions are met or approximated:

1. All actors use identical strategies in negotiating exchanges.
2. Actors consistently excluded from exchanges raise their offers.
3. Those consistently included in exchanges lower their offers.
4. Actors accept the best offer they receive and choose randomly in deciding among tied best offers.
5. Each position is related to, and seeks exchange with, one or more other positions.
6. At the start of an exchange round, equal pools of positively valued resource units are available in every relation.
7. Two positions receive resources from their common pool if and only if they exchange (Markovsky, Willer & Patton 1988:223).

AXIOMS

Four axioms determine the relative power of connected positions and whether they will exchange:

Axiom 1. $$P_{id}(e_d) = \left(\frac{1}{e_d}\right)\sum_{k=1}^{h}(-1)^{(k-1)}m_{idk}$$

Axiom 2. i seeks exchange with j only if $p_i > p_j$, or if $(p_i - p_j) \geq (p_i - p_k)$ for all k related to i.

Axiom 3. i and j can exchange only if each seeks exchange with the other.

Axiom 4. If i and j exchange, then i receives more resources than j if and only if $p_i > p_j$.

APPENDIX: Network Exchange Theory

WEAK AND STRONG POWER

Markovsky et al. (1993) provide an iterative method, GPI^2, used to derive more precise hypotheses.

Step 1. Apply Axiom 2 to determine exchange seeks.

Step 2. Apply Axiom 3 to remove nonmutual exchange seeks.

Step 3. Apply Axiom 1 to each subnetwork that results from Step 2; $p = 1$ for isolates.

Step 4. Re-form the full network with new p values; repeat from Step 1 until values do not change.

If after the above analyses $p_i > p_j$ for actors in the i - j relation, then i has strong power over j, and it is predicted that profits from exchange in this relation will favor i and approach their maximum differentiation. If $p_i = p_j$, then there are exactly two possibilities: either the actors are equal in power, or else one has weak power over the other.

Weak power differences are detected using a probability analysis. The analysis assumes that actors seek exchanges randomly among their potential partners and counts relative proportions of mutual exchange seeks as exchange likelihoods. If i and j have unequal exchange likelihoods, then the actor with the higher likelihood is predicted to have a weak power advantage over the other. This is identified as GPI_3. Examples of its application are provided in Markovsky et al. (1993) and in the theoretical discussion of this article. A computer program for calculating likelihood of inclusion is available at no charge from the second author.

Notes

1. It should be noted, however, that network exchange theory predictions also generally agree with data from exchange situations with greater information restrictions, e.g., Cook, Donnelly, and Yamagishi (1992), Cook and Emerson (1978), and Cook et al. (1983), and also from the setting used by Bienenstock and Bonacich (1993).

2. These conditions are probably sufficient but not necessary to determine whether a network displays strong power. In general, casual inspection often fails to classify networks properly as strong power or weak power. Full application of the GPI method is required.

3. Theoretical integration requires integration of notation systems as well. Markovsky et al. (1993) use the notation $p\{i\}$ to denote the probability of inclusion of position i in an exchange network. But the letter p also occurs in resistance equations to denote profit. To avoid confusion and simplify our notation, we switch to l_i (actor i's likelihood of exchange).

4. C_i is similar to Thibaut and Kelley's (1959) "comparison level for alternatives" or CL_{ALT}, i.e., "the lowest level of outcomes a member will accept in the light of available alternative opportunities" (21). M_i and C_i define the range of possible offers. The model does not assume that actors have objective knowledge of their values. "Best hopes" and "worst fears" need not be reasonable, though actors are likely to refine their estimates as they interact. We have again simplified the notation of earlier presentations of the theory: e.g., Willer, Markovsky & Patton (1989) use $P_{MAX}(A)$ to represent M_i and $P_{CON}(A)$ to represent C_i.

5. Assumptions are evaluated on their effectiveness in producing testable hypotheses that conform well with observation. The assumption that actors exchange when their resistances are equal has been very fruitful in previous studies (Skvoretz & Willer 1993; Willer 1987), including cross-national comparisons (Willer & Szmatka 1993).

6. Cook and Yamagishi (1992) also suggest that the idea of a limit to power use in networks holds promise for a general formula to predict resource distribution. Willer (1987) demonstrat-

ed such generality when he applied the resistance model to a wide variety of network situations both inside and outside the laboratory.

7. Individuals participating in experiments or acting in natural exchange situations will exhibit a range of "best hopes" and "worst fears." This in no way interferes with the model's ability to predict exchange rates. Coalitions among actors are ruled out by the scope conditions of the theory though they may occur often in exchange situations. Erger (1993) has extended the theory to include the effects of coalitions.

8. Markovsky et al. (1993) provide support for this idea. They found that ordinal predictions for weak power networks based on likelihood of being included were more strongly corroborated for experienced than for inexperienced subjects.

9. While simple proportionality is a straightforward way to incorporate likelihood of being included into the resistance model, other specifications are possible. For example, Skvoretz and Willer (1993) take the difference between M_i and P_i, then raise it to the power of l_i. Our model is the simplest expression we could devise of the theoretical idea that actors' worst fears and best hopes in the exchange situation depend on — and are proportional to — the likelihood of their being included in exchanges.

10. The mathematical derivation is available on request from the first author.

11. Markovsky (1988) specifies the conditions under which anchoring will occur: judgments are indeterminate, an anchor is available, and anchors are salient. These conditions are satisfied in experimental tests of network exchange theory. Markovsky's "anchoring proposition" predicts when assimilation as opposed to contrast effects will be observed. According to this proposition, assimilation would be predicted in the present context because degree informs best-hope and worst-fear outcomes, each of which appears on the same scale as the "response" variable, i.e., expected profit. (An anchor on the stimulus scale — as in the temperature example — produces a contrast effect.)

12. An actor's maximum expectation for profit may differ among exchange partners in the same way.

13. In a replication using a different experimental exchange setting, Bienenstock and Bonacich (1993) obtained similar results.

14. Some readers of earlier versions of this article noted the similarity between network exchange and noncooperative game theory (e.g., Harsanyi 1980; Nash 1951; Osborne 1990; Rosenthal & Rubinstein 1984; Rubinstein 1982, 1991). Also, the few experimental tests of noncooperative game theory use experimental situations similar to that used in network exchange experiments but without the complication of network structure (see, e.g., Nydegger & Owen 1974). While intriguing, these similarities mask very real difficulties in applying noncooperative game theory to network exchange. Rubinstein (1982) states the bargaining problem in noncooperative game theory as "Two individuals have before them several possible contractual agreements. Both have interests in reaching agreement but their interests are not entirely identical. What 'will be' the agreed contract, assuming that both parties behave rationally?" (97). He goes on to distinguish this problem from two others: "(i) the positive question — what is the agreement reached in practice; (ii) the normative question — what is the just agreement." Perhaps because of these distinctions, noncooperative game theory places little emphasis on theory testing through experimental or field research and does not fare well in experimental tests. Network exchange theories place more emphasis on the "positive question," on how subjects behave in controlled settings. Experimental results are then used to inform theoretical development in cumulative research programs. Bienenstock and Bonacich have made the most successful use of game theory to analyze network exchange structures.

15. Markovsky et al. (1993) and Skvoretz and Willer (1993) analyze data from these full information experiments. Markovsky et al. (1993) use data from the Stem and Kite networks; Skvoretz and Willer use data from all four experiments. Their analyses are based on all rounds of the experiments. Here we use data from just the last period, which is four rounds long. Although suitable for testing ordinal predictions, using the mean of all rounds in an experiment as an indicator of power is problematic for testing exact predictions. For example, exchange may begin at an even split of the profit pool, 12:12, in early rounds then progress to a stable pattern of 20:4 exchanges. In this case, 20:4 is a good estimate of the power difference

in the relationship. The mean exchange rate for all rounds (about 16:8) would seriously underestimate the magnitude of the equilibrated power difference.

16. Our model requires these assumptions; we do not assume that all naturally occurring social exchanges satisfy these conditions.

17. This system was designed to be relatively "low-tech" and portable to other laboratories. The software is written in Microsoft QuickBASIC (4.5), and PCs are connected in a ring configuration via cables connected to standard serial ports. The ring consists of one master control PC and any number of subject PCs. The program is available from the authors upon request.

18. Equity concerns, for instance, are controlled in the two settings in different ways. If actors feel the exchange situation is unfair, they may refuse to accept the best offer available to them. The full-information setting described solves the potential equity problem by rotating subjects through all positions. Actors disadvantaged in one position know they will be compensated when they rotate through an advantaged position. Restricted-information settings in which subjects typically do not change positions solve the problem by not telling a subject the earnings of his or her partner in order to prevent comparison of subject's rewards with partner's rewards.

19. Because of the differences in intraround negotiation options and total number of rounds between the two settings, we would not expect averages from all rounds to be similar across settings. The restriction to equilibrium rates is essential to the "no setting difference" prediction.

20. In contrast, the first ten A-B agreements for each group varied more widely; the maximum range was 9 ($M = 4.23$, Std. dev. = 2.35). The mean range of the first ten agreements was significantly greater than the mean range of the last ten agreements, $t(10) = 3.09$, $p = .01$.

Persistence and Change in the Protestant Establishment, 1930-1992*

JAMES D. DAVIDSON, *Purdue University*
RALPH E. PYLE, *University of Nevada, Reno*
DAVID V. REYES, *Purdue University*

Abstract

Three Protestant denominations comprising "the Protestant Establishment" (Episcopalian, Presbyterian, and Congregationalist/ United Church of Christ) played a major role in shaping the American way of life. While some scholars claim that Protestant hegemony persists, others argue that we live in a post-Protestant era. We assess these conflicting views by examining the religious affiliations of persons listed in Who's Who in America *in 1930 and 1992. The results indicate that the Protestant Establishment has lost some ground since the 1930s but remains overrepresented among the nation's power and cultural elites. Among other groups, Jews have gained the most. Catholics also have gained, but remain slightly underrepresented among both cultural and power elites. The status of other religious groups is also discussed.*

Three Protestant denominations (Episcopalian, Presbyterian, and Congregationalist [since 1957 United Church of Christ]) have profoundly influenced the social and cultural fabric of American society. These groups emerged as social, economic, and political elites during the first century of American history (Baltzell 1958, 1964; Gaustad 1968; Hutchison 1989). They created an American way of life that reflected their worldviews and worked to their advantage socially, economically, and politically. Because of their prominence among America's elite, they became known as "the Protestant Establishment" (Baltzell 1964).[1]

The Protestant Establishment became so highly institutionalized that some scholars believe its influence upon America's core culture can still be felt (Feagin & Feagin 1993; Greeley 1977; Rossides 1990). While granting that white Anglo-Saxon Protestants (WASPs) are a declining percentage of the total population and that non-WASPs have made some inroads into the upper

*** This research was supported in part by Grant #93-0022 from the Louisville Institute for the Study of Protestantism and American Culture.  Social Forces, September 1995, 74(1):157-175

echelons of American society, these observers emphasize the tenacity of the Protestant Establishment. They contend that an institutionalized system of Establishment-oriented policies and practices persists in most spheres of American life (especially in business and politics), and that the percentage of Episcopalians, Presbyterians, and members of the United Church of Christ (UCC) among the elite is not significantly different from what it was earlier in this century.

However, other scholars argue that major societal changes have eroded the Protestant Establishment's influence (Baltzell 1976, 1991; Christopher 1989; Hammond 1992; Hutchison 1989; Schrag 1970). These writers believe that as a result of forces such as the increased religious pluralism at the turn of the century, the G.I. Bill at the end of World War II, the civil-rights and black power movements of the 1950s and 1960s, and greater cultural pluralism during the 1960s and 1970s, access to positions of social, economic, and political dominance is no longer limited to the Protestant Establishment. They claim that other religious groups (especially Catholics and Jews) have not only achieved socioeconomic parity with Protestants, but they also have penetrated the highest echelons of power and privilege.

Thus, there are sharp differences of opinion on the tenacity or decline of the Protestant Establishment. In an attempt to see what actually happened to the Protestant Establishment between the 1930s and the 1970s, Davidson (1994) recently compared Fry's 1930-31 data from *Who's Who in America* (Fry 1933a, 1933b) with Verba and Orren's 1976-77 study of elites (Verba & Orren 1985). Davidson's results emphasized the persistence of the Protestant Establishment (with Episcopalians, Presbyterians, and UCCs continuing to be overrepresented among the elite), though some groups, especially Jews and Catholics, had made important strides. Davidson also argued that as a result of economic and political developments in the 1980s (e.g., the tendency of the Ronald Reagan and George Bush administrations to appoint WASPs to high political office), the disproportionate influence of the Protestant Establishment probably would persist well into the future. However, Davidson argued that we need more direct longitudinal comparisons of *Who's Who* in the 1930s and 1990s if we are to understand the extent to which the Protestant Establishment persists or has been replaced by a more religiously pluralistic elite. We have just completed such an analysis.

Theoretical Orientation

Building on our earlier work (Davidson 1985, 1994), we use a neo-Weberian, interest group perspective to frame our analysis. This "modified fair shares" perspective (Davidson 1985, 1994; Ryan 1981) stresses the conflict between religious groups. Using policies and practices that we describe below, Episcopalians, Presbyterians, and Congregationalists gained the upper hand over other religious groups and shaped social institutions according to their values and interests. The institutionalization of policies and practices working to WASPs' advantage and the disadvantage of other groups contributed to the persistence of religious inequality, especially in spheres most directly affecting the creation

and distribution of resources (i.e., business and politics). This perspective also recognizes that other religious groups oppose these obstacles, trying to remove or circumvent structural biases against them and to improve their lot in life. As we indicate below, these efforts produce social changes and mobility that sometimes lead to greater access to power and privilege. In the next two sections, we use this theoretical perspective to specify some of the reasons that the Protestant Establishment persists and why it has changed.

WHY THE PROTESTANT ESTABLISHMENT PERSISTS

The Protestant Establishment's prominence in the economic and political spheres became especially important, and it was overrepresented and very influential in most cultural spheres as well (Baltzell 1958, 1964; Feagin & Feagin 1993; Konolige & Konolige 1978). So great was its prominence that writers have used phrases like "the Episcopalianization of the whole upper class" to describe its influence (Baltzell 1958:391).

From this lofty position, the Protestant Establishment was able to shape the nation's public institutions and cultural orientations. Mainline Protestantism's religious and moral perspectives were taken for granted in the nation's public schools (Beale 1938; Lichliter 1946; Moberg 1962; Sweet 1948). Its worldview (the "Protestant ethic") also was built into the nation's economy, especially its emphasis on work and austere attitudes toward people who do not work and are poor (Kluegel & Smith 1986; Tropman 1986). This Anglo-Saxon core culture made it relatively easy for mainline Protestants to achieve and maintain elite status while also making it difficult for other groups to make it to the top (Gordon 1964).

In the process, religious prejudice and discrimination became an important part of American history. In the eighteenth and nineteenth centuries Protestant hostility toward Catholics reduced levels of Irish immigration, prevented Catholics from owning land and voting, and led to high levels of Catholic conversion to Protestantism (Anderson 1970; Clark 1973; Feagin & Feagin 1993; Gaustad 1968; O'Brien 1919). Religious prejudice became even more pronounced during the mid and late 1800s, when groups such as the Know-Nothings and the KKK fought to protect the nation's Protestant heritage against Catholics and Jews (Anderson 1970; Feagin & Feagin 1993). The Immigration Act of 1924 favored northern Europeans while limiting immigration from eastern and southern Europe (Anderson 1970; Feagin & Feagin 1993), where so many Catholics and Jews were coming from. Newspapers and other writings of the time were full of articles extolling the virtues of Anglo-Saxon culture and depicting non-WASPs as intellectually and morally inferior (Curtis 1971; Feagin & Feagin 1993).

But WASP hegemony is not just a thing of the distant past. WASP neighborhoods (e.g., sections of Philadelphia's "Main Line"), prep schools, country day schools, and social clubs persist as major threads in America's social fabric (Baltzell 1958, 1964; Domhoff 1967, 1970, 1983). During the suburbanization era following World War II, upper-income WASP communities still used "gentlemen's agreements," which made it difficult for non-WASPs to obtain housing (*Time* 1960). When President Lyndon Johnson announced changes in the nation's

immigration laws in 1965 (Feagin & Feagin 1993), the influx of new ethnic groups, who were willing to work for minimum wage or less, contributed to the prosperity of established elites and increased tensions among the nation's racial and ethnic minorities. The political conservatism of the 1970s and 1980s, especially evident during the Reagan and Bush administrations, reaffirmed the legitimacy of the WASP way of life ("back to the basics") and reversed many of the gains that racial, ethnic, and religious minorities had made in the 1960s (Feagin & Feagin 1993; Hurst 1992; Phillips 1990). Presbyterian Ronald Reagan was followed by Episcopalian George Bush, and both men tended to select other WASPs for high-ranking appointments with the expectation that these political leaders would create social policies consistent with the Protestant Establishment's core culture.

As these examples suggest, the Protestant Establishment uses several mechanisms to perpetuate its prominence. One mechanism is inheritance. Tax laws encourage elites to pass their wealth along to their sons and daughters (Phillips 1990). That is why every year when *Forbes* magazine lists the nation's 400 wealthiest people, it finds that the single biggest source of wealth is inheritance. Approximately 40% of the nation's wealthiest people have inherited their money from their families (Hurst 1992).

Another mechanism is legacy admissions at elite schools. With their enormous wealth, members of the Protestant Establishment have convinced prep schools and prestigious colleges and universities that it is in their financial best interest to set aside a certain number of positions for their sons and daughters (Karabel 1984; Karen 1991; Levine 1980). WASP elites have been especially adept at getting their children into the most prestigious New England boarding schools and Ivy League colleges. Schools such as Groton, Choate, and Taft are widely known to be steppingstones for WASP children who aspire for admission to Harvard, Princeton, and Yale (Armstrong 1990; Cookson & Persell 1985; Domhoff 1983; Dye 1983; Hurst 1992; Zweigenhaft & Domhoff 1991).

A third mechanism is appointment to high office. Members of the Protestant Establishment often select other Episcopalians, Presbyterians, and UCCs to lead their companies and political administrations (Domhoff 1983). George Bush, an Episcopalian, selected James Baker, another Episcopalian, to be his secretary of state. Then he chose David Souter, another Episcopalian, to be his first nominee to the Supreme Court. Later, he chose Clarence Thomas for the Supreme Court. Thomas was married to an Episcopalian and, though raised Catholic himself, was an active member of an Episcopal church in Virginia at the time of his appointment.

Stressing a status persistence viewpoint,[2] we believe that the Protestant Establishment remains largely intact, with Episcopalians, Presbyterians, and UCCs continuing to be overrepresented among the nation's elite, especially in the economic and political spheres, which have the most direct impact on the creation and distribution of scarce resources (Alba & Moore 1982; Davidson 1994; Domhoff 1983; Dye 1983).

CHANGE

But we also expect at least some decline in Protestant hegemony. There has been some movement away from cultural norms promoting a Protestant Establishment (Carroll & Roof 1993; Hammond 1992; Reed 1988). Ethnocentric religious barriers that previously limited the participation of non-WASPs in important economic, political, and cultural spheres have been challenged, and in some cases removed (Baltzell 1991; Christopher 1989). Since the 1960s, the nation has articulated an alternative to the Anglo conformity model that fostered an emphasis on assimilation (Gordon 1964). The increasing emphasis on multiculturalism is an expression of a growing acceptance of ethnic and religious pluralism. In this respect, the nation is more universalistic, and less religiously particularistic, than it was in previous eras, which enables formerly marginalized groups to move into prestigious positions once reserved for members of the Protestant Establishment. We have had Catholic and Baptist presidents, though Jews have not yet attained the Oval Office.

Many sociologists of religion (Carroll & Roof 1993; Finke & Stark 1992; Hammond 1992; Johnson 1985) argue that the decline in the size of the most prestigious mainline Protestant denominations indicates the wavering influence of an older Protestant Establishment. A number of analysts also suggest that denominations are no longer as important as they once were (Carroll & Roof 1993; Christopher 1989; Hammond 1992; Wuthnow 1988). Wuthnow, for example, argues that educational levels, rather than religious affiliation, separate people into distinct status categories. Declining Protestant-Catholic-Jewish tensions after World War II and increasing ecumenism and interfaith contact also imply a lessening of religious divisions (Herberg 1960; Roof & McKinney 1987). More frequent religious intermarriage indicates that traditional religious boundaries have lost some of their impact on patterns of social interaction (Kalmijn 1991).

Social mobility among non-Protestants reinforces the claim that religious distinctions are on the decline. In the last 60 years, Catholics and Jews have made impressive gains in their socioeconomic standing. Jews have made significant progress in attaining positions of prominence after World War II, especially in intellectual and cultural spheres (Alba & Moore 1982; Lieberson & Carter 1979; Weyl 1966). Descendants of East European Jews moved from the ghetto to the suburb in two generations (Baltzell 1964; Herberg 1960; Sklare & Greenblum 1979). Catholics also substantially improved their socioeconomic position, having met or surpassed Protestants on most measures of economic status (D'Antonio et al. 1989; Gallup & Castelli 1987; Glenn & Hyland 1967; Greeley 1977; Marger 1991; Roof 1979). Non-Protestants have gained a foothold in important cabinet and political posts (Mintz 1975), and they are increasingly represented on prestigious policy commissions and cultural boards (Christopher 1989; Zweigenhaft & Domhoff 1982).

Some of the gains made by non-WASPs can be attributed to the decline of discriminatory measures. Civil-rights legislation of the 1960s outlawed job discrimination on the basis of ascribed characteristics such as race or religious background (Alba 1990; Marger 1991). Formal religious quotas at elite eastern colleges have been removed, as have restrictive policies at the most exclusive

metropolitan social clubs (Baltzell 1986). Affirmative action policies have worked to broaden the ethnic composition of those in professional spheres (Zweigenhaft & Domhoff 1991). These and other measures have removed impediments that prevented the advance of non-WASPs.

Gains made by non-WASPs also result from changes in the structure of education. To a large degree, education has served as the enabling mechanism propelling Catholics and Jews into positions of influence during the last fifty years. The G.I. Bill of 1944, for example, broke down ethnic barriers to college opportunity and gave a boost to the descendants of immigrants who otherwise would not have had the opportunity to attend college (Christopher 1989; Keller 1991). Higher education enrollments in 1985 were more than eight times what they were in 1940 (Kingston & Lewis 1990). Recently, there has been a decline in the proportion of Eastern prep school graduates admitted to Ivy League schools (Cookson & Persell 1985; Zweigenhaft & Domhoff 1991), thus limiting the influence of the most prestigious Protestant boarding schools.

Advances made by non-Protestant groups also result from structural changes in the economy. Some analysts argue that economic expansion after World War II and the attendant increase in bureaucratization and scientific specialization have led to greater professional opportunities for capable individuals from diverse backgrounds (Keller 1991; Reed 1988). The movement from an emphasis on ascription to an achievement orientation favors talented ethnic groups over old family descendants (Jaher 1980). Baltzell (1986) suggests that after World War II we witnessed a change from a prewar social structure dominated by a Protestant elite to a classless bureaucracy rewarding educational achievement. As a consequence, non-Protestants have increasingly moved into prestigious educational, legal, and medical positions, although their representation as corporate officers remains limited (Alba & Moore 1982; Sturdivant & Adler 1976).

The cumulative effect of these processes is that non-Establishment groups, especially Catholics and Jews, have made significant progress in their overall socioeconomic status. This progress does not guarantee access to elite status. However, increasing percentages of Catholics and Jews probably have attained elite positions, especially in cultural fields, such as education or arts and letters, less so in business and politics, where we think the Protestant Establishment continues to be most overrepresented.

Methods

This study analyzes the religious affiliations of individuals listed in *Who's Who in America* in 1930-31 and 1992-93. *Who's Who* is probably the best known, and most highly regarded, listing of persons who have achieved special prominence or distinction in their chosen fields. It is probably the best source of information on the religious preferences of elite individuals, for whom survey data are rare.

Two classes of individuals are included in *Who's Who*: persons of significant achievement in various lines of endeavor and those included because of the official positions they occupy.[3] There is some degree of overlap between the categories. *Who's Who* editors acknowledge that most persons included because

of their official positions would also be admitted because of their achievements (Marquis Who's Who 1992).

There has been a gradual increase in the proportion of the American population listed in *Who's Who,* rising from 2.40 names per 10,000 in 1930 to 3.21 names per 10,000 in 1992. However, *Who's Who* editors insist that there has been a consistent application of admission criteria over the years and explain periodic fluctuations in the inclusion rate as a result of expansion and contraction of occupational fields (Larson 1958). The criterion of "reference interest" has been applied consistently over the years. While *Who's Who* is not without its limitations (Lieberson & Carter 1979; Pyle 1995), this roster of eminent Americans serves as a useful tool for studying changes in the denominational preferences of elite Americans from the 1930s to the 1990s.

A number of other studies have analyzed the religious preferences of *Who's Who* listees (Ament 1927; Davis 1953; Fry 1933a, 1933b; Huntington & Whitney 1927; Kirk 1957; Newcomer 1955; Selth 1987; Weber 1933). Of all these, Fry's is the most complete. Fry tabulated religious and occupational information on everyone listed in the 1930-31 edition of *Who's Who* (*N* = 29,623).

We selected a 1-in-20 systematic sample of the approximately 80,400 names listed in the 1992-93 edition. Our large *N* of 4,018 also minimizes sampling-based measurement error and provides the best available basis for estimating the contemporary status of the Protestant Establishment.[4]

Fry's 1930-31 analysis indicated that 56% of the entries reported a denominational preference. In our 1992-93 sample, 34% listed one. While some of this difference might be related to an increase in the percentage of the U.S. population reporting no religious preference (Glenn 1987; Roof & McKinney 1987), the difference probably has more to do with an increased tendency for elites to withhold personal information in public documents such as *Who's Who.* The decline in religious reporting is consistent with a reduction in the reporting rate for other personal data, such as listees' home addresses, club memberships, and political affiliations (Priest 1982; Pyle 1995; Selth 1987).

To explore the status of religious groups in different spheres, we put *Who's Who* listees in two broad occupational categories, power elites (occupations with considerable control over the creation and distribution of economic and political resources) and cultural elites (fields with more influence over ideas and cultural symbols). Power elites included bankers, businessmen, politicians, diplomats, judges, lawyers, and military officers (32% of all elites in 1930 [*N* = 9,314]; 48% in 1992 [*N* = 1,884]). Cultural elites included educators, scientists, doctors, engineers, editors and authors, artists and actors, and religious and social workers (68% of all elites in 1930 [*N* = 19,698]; 52% in 1992 [*N* = 2,049]). Those not falling within either of these divisions were left out of the occupational analysis (2.1% of the original sample in both years).

Z scores are used to indicate significant differences in the religious affiliations of *Who's Who* entries in 1930 and 1992. Since these comparisons do not take into account changes in denominational market shares among the general population over time (Finke & Stark 1992; Roozen 1993), ratios also are used to indicate denominational affiliation in *Who's Who* relative to denominational representation in the general population in the 1930s and 1990s. These ratios provide an even better indication of stability and change in denomination-

al representation in *Who's Who*. Ratios were calculated for all *Who's Who* listees and for those in the power elite and cultural elite. The 1926 census of religious bodies was used to determine denominational membership for the U.S. population during the earlier period (U.S. Bureau of the Census 1930). Since the census did not report Jewish congregational membership, Ament's (1927) estimate of Jewish membership was substituted.[5] We also used Ament's figures for Mormons in the 1926-27 *Who's Who* because Fry did not provide data on the number of Mormons in the 1930-31 edition. The combined 1988-91 General Social Surveys were used to determine denominational preferences for the general population in the 1990s (Davis & Smith 1991).

Findings

Overall, the results are quite consistent with our expectations. Though Episcopalians, Presbyterians, and UCCs as a group have lost some ground since the 1930s, they remain overrepresented among the nation's elite. They are slightly more prominent among power elites than cultural elites, though they are overrepresented in both spheres. Among other historical elites, Unitarian-Universalists are less prominent in the 1990s than they were in the 1930s but remain overrepresented in all spheres. Quakers have lost status among power elites but have gained among cultural elites. Catholics and Jews have made the most progress. Jews are now overrepresented among both power and cultural elites. In spite of Catholics' impressive gains, they remain underrepresented in both spheres. Among other Protestant groups, Baptists are most underrepresented of all and have declined since the 1930s. Disciples of Christ have also lost ground. Lutherans have gained, while United Methodists and the Reformed Church have had mixed experiences. Mormons have gained, and Christian Scientists have about the same stature as they did earlier.

Table 1 shows the religious affiliations of individuals in *Who's Who* in 1930-31 and 1992-93. In 1930-31, the Protestant Establishment accounted for 53.5% of all elites who reported a religious preference; in 1992-93, it accounted for 35.1% (a 34.4% decline). Episcopalians were the most tenacious of the three Protestant Establishment denominations; UCCs declined the most during the period. Episcopalians comprised 21.94% of the entries in 1930 and 18.04% in 1992 (not significant at .001). Presbyterians declined from 20.31% to 13.91% (a significant difference of 31.5%). UCCs declined from 11.29% to 3.19% (a 71.7% difference, which was significant).

Among other elite groups, Unitarians were significantly less prominent in the 1990s than they were in the 1930s. Although there were fewer Quakers among the elite, this decline was not significant at the .001 level.

Jews and Catholics gained the most (difference of proportion measures were statistically significant in both cases). Together, Jews and Catholics were only 5.76% of all *Who's Who* listees in 1930; by 1992, they were 35.44% (6.2 times as many). Jews comprised 1.31% of the entries in 1930, but 12.32% in 1992 (9.4 times as many).[6] Catholics rose from 4.45% of all entries in 1930 to 23.12% in 1992 (5.2 times as many).

* 1930-92 difference significant $p < .001$

Among other religious groups, only Lutherans and Mormons increased in prominence. Baptists, Disciples of Christ, United Methodists, the Reformed Church, and Christian Scientists declined.

Table 2 shows the ratio of each denomination's representation in *Who's Who* to its representation in the U.S. church population (exact proportional representation is defined as 1.00). The Protestant Establishment groups were overrepresented in both the 1930s and the 1990s. Episcopalians are even more highly overrepresented among elites today than they were in the 1930s. In 1930 Episcopalians had 6.34 times as many listees among America's elite as we might

expect based on their distribution in the U.S. population. In 1992, they had 7.04 times as many listees. This increase was not matched either by Presbyterians, who declined from 3.35 to 2.75, or by UCCs, who declined even more (from 5.65 to 2.62). Despite these declines, Presbyterians and UCCs remain overrepresented among eminent Americans.

The other elite groups, the Unitarian-Universalists and Quakers, are still overrepresented. Unitarian-Universalists fell from a proportional ratio of 20.62 among the elites in 1930 to one of 9.60 in 1992. Quakers, on the other hand, are now more overrepresented than they were 60 years ago (up from 4.78 to 6.50).

The most dramatic increase was experienced by Jews. Though underrepresented in 1930 (only .73 as many entries as one might expect), Jews are now six times as likely to be represented among elites as they are to be found in the total population. Catholics also have gained. However, Catholics, who had only .13 times as many entries as one might have expected in 1930, were still underrepresented in 1992 (their ratio was .85).[7] Although Catholics have achieved parity with Protestants in overall socioeconomic status, they have not yet reached parity among elites.

With the exception of Christian Scientists (who are slightly overrepresented among elites and have about the same stature today as they did earlier), all other groups are underrepresented, as they were in the 1930s. There are proportionately more Lutherans, United Methodists, members of the Reformed Church, and Mormons among elites today than there were about sixty years ago. Baptists and Disciples, however, are less prominent now than they were in the 1930s.

Table 3 also shows denominational representation in *Who's Who* as a ratio proportional to general church membership, while distinguishing between power elites and cultural elites. Establishment groups remain overrepresented in both spheres and, as expected, are slightly more prominent among power elites than among cultural elites.

Episcopalians set themselves apart from other Establishment groups once again. Episcopalians were more prominent among power elites than among cultural elites in both periods. In 1930 they had 7.87 times as many leaders in business and public policy areas as might be expected based on their proportion of the total U.S. church membership; in 1992, they still had almost as many (7.41). There were 5.59 times as many Episcopalians as one might expect among leaders in cultural fields in the 1930s; in 1992, there were even more (6.44). Presbyterians also were more prominent among power elites than among cultural elites in both the 1930s and the 1990s. They had a proportional ratio of 3.60 among power elite entries in 1930; by the 1990s, they had a somewhat lower one (2.82). They had a proportional ratio of 3.23 among cultural elites in 1930; now they have one of 2.62. UCCs are different. In 1930, they were more overrepresented as cultural leaders (with a ratio of 6.20) than among power elites (with a ratio of 4.49). In 1992 they were about equally represented in both spheres (with ratios of 2.57 among business and political leaders and 2.53 among cultural leaders).

Unitarian-Universalists and Quakers were the most highly overrepresented of all religious groups among cultural elites. In 1992 these groups, respectively, had 14.8 and 12.7 times as many members among cultural elites as they had in

the U.S. population as a whole. Though they were somewhat less prominent in the 1990s than in the 1930s, they remained the most culturally eminent groups in our society. Both groups also were overrepresented among power elites, but their prominence in economic and political arenas has waned considerably over the years.

Jews were slightly more prominent (though underrepresented) among power elites than cultural elites in the 1930s (.88 vs. .66). By 1992 Jews were noticeably more prominent in cultural fields than in business and politics (7.23

vs. 5.17). Catholics were about equally underrepresented in both spheres in the 1930s (.15 vs. .12). By the 1990s they were slightly more present among power elites than among cultural elites (.92 vs. .74).

Christian Scientists have been, and still are, more prominent among power elites than among cultural elites.[8] All other groups are underrepresented in both arenas, although Lutherans have gained considerable ground. Mormons also have gained. United Methodists and members of the Reformed Church have gained a bit among power elites, but their prominence among cultural elites has remained virtually the same. Baptists and Disciples of Christ have declined the most in both spheres.

Conclusions

Our data show that the Protestant Establishment has lost some ground relative to other groups since the 1930s, but contrary to the impression left by much of the literature declaring "the decline of the WASP," Establishment groups remain overrepresented by a considerable margin (by a factor of seven among Episcopalians and almost three among Presbyterians and UCCs). Episcopalians, Presbyterians, and UCCs no longer have the nearly exclusive access to positions of power, privilege, and prestige they once had. Their prominence in virtually all social hierarchies has declined a bit since the 1930s. However, Episcopalian influence has remained remarkably stable among power elites and has even increased among cultural elites. Though Presbyterians and UCCs have lost a bit more status, they remain overrepresented among the nation's power and cultural elites by two to three times their distribution in the total population.

The other elite groups, the Unitarian-Universalists and Quakers, are not as prominent as they used to be, but they remain overrepresented among both power and cultural elites (especially cultural elites, where they appear at about twice the Episcopalian rate).

The data also indicate that America's elites are more religiously diverse than they were about sixty years ago. While Episcopalians, Presbyterians, and UCCs were 53% of all elites in the early 1930s, they now comprise only 35%; other groups are now 65% of all elites. Jews and Catholics especially have made major strides in their climb toward the top of our society. Both groups have more access to power and privilege today than they ever had. Jews are now overrepresented among both power elites and cultural elites relative to their distribution in the total population. As we forecasted, they are more prominent among cultural elites than among power elites. Though Catholics have gained, they remain underrepresented in both spheres, especially among cultural elites.

Christian Scientists retain a presence among power elites. Lutherans have gained considerably in both spheres, as have Mormons, though both groups are underrepresented. United Methodists and members of the Reformed church have gained among power elites, but their prominence among cultural elites has remained stable. Baptists and Disciples of Christ have lost the most ground in both areas.

IMPLICATIONS

These findings have several implications. First, they are consistent with claims of writers such as Davidson (1994), Feagin and Feagin (1993), Greeley (1977), and Rossides (1990), who have emphasized the tenacity of WASP hegemony. Together, these studies suggest that members of the Protestant Establishment, and other religious elites, like most superordinate groups, want to maintain their power and privilege. Our results emphasize the continuing influence of groups that have played prominent roles in the shaping of the American way of life — a fact that seems to get lost among the louder voices declaring that Protestant hegemony has ended.

It is too early to declare, as writers such as Christopher (1989) have, that the Protestant Establishment is a thing of the past and that we are now living in a post-Protestant era. All three of the historically important Establishment groups remain overrepresented among both power and cultural elites. Even if their current rates of decline continue, these groups will have more than their fair share of influence in American society for several more decades.

Our study's emphasis on the different experiences of religious groups causes us to question the now-common claim that there is an ongoing convergence among Protestant denominations (Hammond 1992; Wuthnow 1988) and even among mainline religions (Roof & McKinney 1987). There is little evidence in this study to indicate a dramatic equalization of denominational status, as is claimed by convergence analysts. On the contrary, there is considerable evidence that denominational and religious family boundaries continue to be important factors that influence people's life chances.

These observations suggest two lines of further inquiry. There is a need for studies focusing attention on the way members of established religious groups maintain their prominence, especially among power elites. Studies of the methods by which members of the Protestant Establishment protect their advantages in the face of opposition would advance sociologists' understanding of how religion contributes to social inequality. To what extent do groups rely on mechanisms such as inheritance, legacy admissions, and appointments to high office to maintain their status? Do Establishment groups rely on different methods in business and politics than in cultural arenas such as higher education and the arts? We also need longitudinal studies of the implications of being among the elite. Do members of the Protestant Establishment who enjoy elite status today have the same opportunities to advance their self-interests that older generations of WASPs did? Or, as some writers claim, are they more limited in what they can do to maximize their own well-being and to impose their worldviews on others? Studies of the freedoms and constraints associated with elite status also would further our understanding of religion and social inequality.

Within an overall context of persistence, it also is true — probably as a result of the many developments we discussed in our theoretical section — that the Protestant Establishment no longer has the nearly exclusive control it once had over the nation's cherished resources. In addition to declining in the total population (cf. Finke & Stark 1992; Roof & McKinney 1987), it also is declining among the nation's power and cultural elite.

But the three Establishment groups, as well as the Unitarian-Universalists and Quakers, have had different experiences, which need to be examined more carefully in future studies. We need more research on how Episcopalians have held on most tenaciously, even gaining prominence in some areas, in the face of minority efforts to challenge their prominence and scholarly claims that denominations have lost their meaning. We also need additional studies of Presbyterians and UCCs to see how, despite their small numbers, they have preserved their influence, but also why they have failed to keep up with Episcopalians. How have Quakers gained in cultural prominence since the 1930s, while losing some ground in economic and political arenas?

Our findings also reaffirm many other studies indicating that Jews and Catholics have made important strides toward the top of our society. These two groups have come a long way since the 1930s. But perhaps more important, our study indicates how different these two groups' experiences have been. Jews, only 2% to 3% of the population, have made the most progress, going from marginal status among both power and cultural elites to being overrepresented in both areas, especially the cultural area. In the face of historical and lingering anti-Semitism, Jews have made remarkable gains and achieved eminence in both power and cultural circles. While Catholics, about one quarter of the U.S. population, have gained in overall socioeconomic status and in access to elite status, they still are underrepresented among elites. They may still struggle against subtle forms of anti-Catholicism, but at their current rate, they are likely to achieve parity in another decade or two. Comparative studies of these two groups — the opposition they have experienced and the gains they have made — would enhance our understanding of dominant-minority relations in general and religious superordination and subordination in particular.

Our results also suggest the need to study the other groups we have examined. Lutherans, who have gained the most among Protestant groups, and Baptists and Disciples, who have lost the most, would be of particular interest. How do Lutherans' success experiences compare with those of Catholics and Jews? What factors have contributed most to the decline of Baptists and Disciples?

Finally, this study documents important comparisons between the 1930s and 1990s. However, it does not tell us much about the rates of change during the intervening decades. Has the Protestant Establishment been able to maintain its prominence at approximately the same rate throughout all of the last five or six decades? How prominent were the Establishment groups in the 1950s compared to the 1970s? Is it true, as Christopher (1989) and others have suggested, that the Establishment lost ground most rapidly during the last 20 years? What about Jews and Catholics during the intervening years? Has their progress been steady, or uneven? Did they gain more rapidly between the 1930s and the 1950s, the 1950s and the 1970s, or the 1970s and the 1990s? How similar or different have their trajectories been during these decades? These questions need to be explored if we are to fully understand persistence and change in the Protestant Establishment and among other religious groups that will shape the American way of life in the years ahead.

Notes

1. Our analysis focuses on the three major groups composing the Protestant Establishment (Episcopalians, Presbyterians, and UCCs). However, we also will report data on two other religious groups that played major roles in shaping the nation's cultural orientations during the eighteenth and nineteenth centuries but have never been considered part of the Protestant Establishment: Unitarians (later Unitarian-Universalists) and Quakers (the Society of Friends).

2. Contrary to the emphasis of a status attainment explanation for mobility (Blau & Duncan 1967; Knottnerus 1987), a status persistence approach stresses the extent to which life chances are passed on across generations (Rossides 1990; Rytina 1989).

3. Persons selected on the basis of positions they hold include all members of Congress and the cabinet, federal judges, department heads, ambassadors, heads of the major universities, principal officers of the largest businesses, chief ecclesiastics of the major religious denominations, and others chosen because of incumbency in positions of responsibility (Marquis Who's Who 1992).

4. *Who's Who* entries were placed in the denominational categories shown in Table 1. The "all others" category includes groups with only a few listees and persons who indicated their affiliation as "Christian" or "Protestant."

5. The 1926 census figure for Jews is an estimate of the number of those of the Jewish faith living in communities where there was a congregation; consequently, this figure does not indicate the congregational membership (Engelman 1947; Goldstein 1981). Ament estimated that in 1927 Jews represented 1.8% of the total U.S. church membership.

6. Fry (1933b) argues that some Jews were probably reluctant to identify their religious preference in the 1930s. Assuming this is true, the real Jewish figure in 1930 might have been slightly higher than 1.31, and the actual difference between the 1930 and 1992 figures might be slightly smaller than the one reported in Table 1.

7. The Catholic index for 1930 is based on census figures showing that, after Jewish congregational membership is included, Catholics comprised about 34.2% of the U.S. church population. Ament's (1927) data suggest that this figure is inordinately high. We are inclined to think that Ament's estimate of Catholic membership (20.8% of the U.S. total in the mid 1920s) is a better approximation of the true Catholic figure. If Ament's estimate is substituted, the 1930 Catholic index of representation is .21 instead of .13.

8. The small number of Christian Scientists in the *Who's Who* sample accounts for their absence among cultural elites in 1992.

The Changing Basis of Competition in Organizational Populations: The Manhattan Hotel Industry, 1898-1990*

JOEL A.C. BAUM, *University of Toronto*

Abstract

Density-dependence theory cannot account for the widely observed pattern of proliferation and concentration in organizational populations. Although density dependence provides an explanation for initial proliferation, it cannot explain subsequent concentration because it does not allow some organizations to become dominant competitors. To address this basic limitation, I combine density dependence with three ecological models that permit size-based competitive asymmetries among a population's members and let the intensity of competitive processes vary over time. My analysis shows that Manhattan hotels of different sizes generate and experience different strengths of competition and that size-based competitive processes increase in strength over time, contributing to industry concentration. Separating empirically the effects of low-density conditions that occur early and late in a population's history also clarifies tests of density dependence in populations that have evolved beyond their peak density.

The evolutionary trajectories of diverse organizational populations appear to follow a common path. The number of organizations grows slowly initially, then increases rapidly to a peak. Once the maximum is reached, the number of organizations declines as one or a few large organizations come to dominate a much larger number of small organizations. Populations of newspaper publishers, labor unions, breweries, and banks, to list only a few, follow this basic pattern (Hannan & Carroll 1992). The application of ecological models of competition to explain this pattern has been a frequent topic in recent research in organizational sociology. An impressive array of evidence has been assem-

* *This research was conducted, in part, while the author was associate professor of management at the Stern School of Business, New York University. bled linking the evolutionary trajectories of organizational populations to four ecological models of competition: *density dependence* (Hannan & Carroll 1992; Hannan & Freeman 1989), *mass dependence* (Barnett & Amburgey 1990), *size-localized competition* (Baum & Mezias 1992; Hannan, Ranger-Moore & Banaszak-Holl 1990), and *resource partitioning* (Carroll 1985; Carroll & Swaminathan 1992).

Among these models, density dependence is used most frequently in empirical research. This model focuses on population density, the number of organizations in a population, to explain the dynamics of mutualism (i.e., organizations enhancing each other's fates) and competition (i.e., organizations diminishing each other's fates) that underlie the growth trajectories of organizational populations. Although Hannan and Carroll (1992), Hannan and Freeman (1989), and others provide empirical support for the density-dependence model in a variety of organizational populations, density dependence provides an explanation only for the shape of the growth trajectory of organizational populations to their peak size, *not* for their subsequent domination by a few large organizations, i.e., concentration (Carroll & Hannan 1989). Density-dependence theory and research treat competition as a property of populations and assume that all of a population's members contribute to and experience competition equally (e.g., Winter 1990:286). This assumption ignores the asymmetries in competitive relationships that occur in most competitive situations (Carpenter et al. 1988). Since no organization or small group of organizations can dominate competition, the density-dependence model predicts logistic growth to an equilibrium level, but not the concentration that characterizes older populations. The tendency of organizational populations to become concentrated is of substantive interest, however, because it has implications for the structure of the distribution of power in organizational populations and communities (Hannan, Ranger-Moore & Banaszak-Holl 1990).

Notably, although density-dependence theory predicts logistic growth of populations only to their peak size, it is commonly tested in populations that have evolved well beyond their peak density (e.g., Hannan & Carroll 1992). This complicates density-dependence interpretations in two ways. One is that the meaning of population density varies greatly between early and later periods of a population's history. In early low-density conditions no organization or small group of organizations dominates and new entrants are typically similar to established organizations. By comparison, in late low-density conditions, one or a few large organizations often dominate substantial portions of the market, and organizations tend to differ considerably in size and strategy. Thus, increasing concentration diminishes the adequacy of population density as a proxy for the aggregate effects of a population on competition over the population's history (Winter 1990:289).[1] The other is that, when density is equally low early and late in a population's history, the legitimacy interpretation of the coefficient for the linear density term is unclear: Although early low density has a specific meaning in density-dependence theory (i.e., legitimation), late low density has no meaning at all.

The purpose of this article is to enrich our understanding of the influence of competitive processes on the evolutionary trajectories of organizational populations by combining density dependence with ideas from complementary models of ecological competition that allow different-sized organizations to

generate and experience competition of different strengths. Organizational size, arguably the dominant variable in organizational sociology (e.g., Scott 1987), is the most notable organizational characteristic affecting competitive processes neglected by density-dependent explanations for population dynamics. Mass dependence, size-localized, and resource partitioning models of ecological competition each address different aspects of the role of organizational size in competitive dynamics. Theory and research on these models suggests that the strength of competition generated and experienced by organizations in a population depends not only on the prevalence (i.e., density) of other organizations in the population, but on their sizes as well. By incorporating size-based competitive asymmetries, these models help explain the evolution of concentrated organizational size distributions.

In the original statement of density-dependence theory in organizational ecology, Brittain and Freeman (1980) identify important changes in the basis of competition that take place over the history of an organizational population. This article highlights the changing basis of competition, too, by examining how the strengths of competitive processes specified by density- and size-based models depend on the evolutionary point of the population. The predicted temporal variations in competitive processes contribute further to an explanation for the evolution of concentrated populations. I examine changes over time in the basis of competition in an analysis of organizational failure rates in the Manhattan hotel industry from 1898 to 1990.

Thus, in contrast to past ecological research, which treats the effects of competition as time-invariant (Isaac & Griffin 1989), I permit the effects of competitive processes to vary over a population's history. My approach also helps clarify tests of density dependence in populations that have evolved beyond their peak density by including variables that capture the effects of increasing organizational size variation on competitive processes directly in the analysis and by separating the effects of early and late low-density conditions empirically.

Ecological Models of Competition

DENSITY-DEPENDENT COMPETITION

The density-dependence model focuses on population density, the number of organizations in a population, to explain the dynamics of organizational populations. Hannan (1986) and his colleagues (Hannan & Carroll 1992; Hannan & Freeman 1989) propose that initial increases in population density produce mutualism by raising the institutional legitimacy of a population. The capacity of a population's members to acquire resources increases greatly when those who control resources take the organizational form for granted. However, as a population continues to grow, the interdependence among a population's members becomes competitive. When there are few organizations in a population, competition with others for scarce common resources can easily be avoided. But, as the number of potential competitors grows, avoidance becomes more difficult. Combined, the mutualistic effects of initial increases in density

and the competitive effects of further increases suggest curvilinear relationships between population density and organizational founding and failure rates.

Density-dependence theory predicts that growing density intensifies competition at an increasing rate. When there are few organizations in a population (relative to the abundance of resources), the addition of an organization increases the frequency and strength of competitive interactions only slightly, if at all, because competition with others for scarce common resources can easily be avoided. But as the number of population members grows (relative to the abundance of resources), avoidance becomes more difficult and the addition of an organization greatly increases the intensity of competition. Support has been found in a wide variety of empirical settings for the prediction that the intensity of competition increases at an increasing rate with population density (Hannan & Carroll 1992; Hannan & Freeman 1989; Singh & Lumsden 1990). Thus, the density-dependence model makes the following prediction:

Hypothesis 1a. Density dependence: The organizational failure rate increases at an increasing rate with increases in population density.

MASS-DEPENDENT COMPETITION

Density-dependence theory assumes that the intensity of competition experienced by an organization depends on the number of organizations in a population, regardless of their sizes. Small population members are assumed to place the same burden on the carrying capacity of the population as large members (Barnett & Amburgey 1990; Winter 1990). Yet there is broad agreement among scholars that large organizations secure a competitive advantage over smaller rivals as a result of their superior access to resources (e.g., Aldrich & Auster 1986; Starbuck 1965; Thompson 1967), greater market power (e.g., Bain 1956; Caves & Porter 1977; Edwards 1955; Pfeffer & Salancik 1978), and economies of scale and scope (e.g., Scherer & Ross 1990). If not all organizations in a population are equal competitors, then population density may not provide the most precise measure of competition faced by the organizations in a population (Baum & Mezias 1992).

To account for the greater potential competitive strength of a population's larger members, Barnett and Amburgey (1990) propose modeling the effects of population mass, the aggregate of the sizes of all organizations in a population (i.e., population density weighted by organizational size), along with population density. In contrast to density dependence, which examines whether larger *numbers of organizations* generate greater competition, mass dependence examines whether larger *organizations* generate greater competition. If larger organizations are stronger competitors, then, after accounting for the effects of population density, increases in population mass should have a competitive effect.

By permitting competitive strengths of organizations to vary as a function of size, mass-dependent competition allows larger organizations to dominate their populations. Thus, a key evolutionary implication of mass-dependent competition is that, over time, individual large organizations may displace, through competition, some of their population's size in numbers, resulting in

concentrated organizational size distributions (Barnett & Amburgey 1990:80). Large organizations may therefore be central to organizational ecology because they have a disproportionate influence on population dynamics (Barnett & Amburgey 1990).

Studies of mass-dependent competition present mixed findings. Some find competitive effects (Banaszak-Holl 1992; Baum & Mezias 1992; Hannan & Carroll 1992). Others find either no effect (Hannan & Carroll 1992) or a mutualistic effect (Barnett & Amburgey 1990). However, contradictory findings appear attributable to data limitations (Hannan & Carroll 1992:130-31) or significant features of the study population (Barnett & Amburgey 1990:98-99). The mass-dependent competition model makes the following prediction:

Hypotheses 2a. Mass dependence: The organizational failure rate increases with increases in population mass.

SIZE-LOCALIZED COMPETITION

Density-dependence theory assumes that each organization in a population competes with all other organizations in the population at an equal intensity (Baum & Mezias 1992). In the original statement of population ecology, however, Hannan and Freeman (1977:945-6) challenge this view. Following a long tradition in organizational sociology, they propose that organizations of different sizes use different strategies and structures. As a result, although organizations of different sizes are engaged in similar activities, large and small organizations depend on different mixes of resources. Therefore, Hannan and Freeman conclude that organizations compete most intensely with organizations of similar sizes. For example, if large and small organizations depend on different resources (e.g., large hotels depend on conventions while small hotels depend on individual travelers), then patterns of resource use will be specialized to segments of the size distribution. Consequently, competition between large and small organizations will be less intense than competition among large or among small organizations. Large organizations may, however, pose a threat to medium-sized organizations. Whatever strategy medium-sized organizations adopt to compete with large organizations will make them more vulnerable to competition from small organizations and vice versa. Therefore, the emergence of large organizations is likely to trigger a decline in the number of medium-sized organizations, while small ones flourish as their most intense competitors are removed from the environment.

Thus, analogous to the mass dependence model, a key evolutionary implication of size-localized competition is that, over time, individual large organizations may outcompete their smaller rivals, resulting in a more concentrated population. The main difference between the two models is that mass-dependent competition predicts the evolution of skewed (e.g., log-normal) size distributions (Barnett & Amburgey 1990) and size-localized competition predicts the evolution of bimodal size distributions (Hannan, Ranger-Moore & Banaszak-Holl 1990). Recent studies of Manhattan banks (Banaszak-Holl 1992), Manhattan hotels (Baum & Mezias 1992), and U.S. health maintenance organizations (Wholey, Christianson & Sanchez 1992) provide empirical evidence of size-

localized competition. The size-localized competition model makes the following prediction:

Hypothesis 3a. Size-localized competition: The failure rate of organizations of a given size increases with increases in the number of similarly sized organizations.

RESOURCE PARTITIONING

In work related closely to Hannan and Freeman's (1977) size-localized competition model, Carroll (1985) proposes that competition among large, generalist organizations in a population to occupy the center of the market frees peripheral resources that are most likely to be used by small, specialist members of the population. Carroll (1985) refers to the process generating this outcome as resource partitioning. The resource partitioning model implies that, in concentrated markets with a few large generalists, small specialists may be able to exploit more of the available resources without engaging in direct competition with larger, generalist organizations. This yields the prediction that increasing market concentration increases the failure rate of large, generalist organizations and lowers the failure rate of small, specialist organizations. Notably, the resource partitioning model offers one possible basis for size-localized competition and the evolution of concentrated, bimodal organizational size distributions: Large organizations secure the advantages of generalism, small organizations the advantages of specialism, and midsized organizations the liabilities of both (Meyer 1990). Thus, resource partitioning may constitute a subclass of size-localized competition. However, specification of concentration as a cause of size-localized competition provides a distinct insight.

In a study of newspaper organizations, Carroll (1985) found that, during the process of concentration, the failure rate of large, generalist newspapers increased while the failure rate of small, specialist newspaper organizations decreased, providing evidence that resource partitioning was at work. More recently, Carroll and Swaminathan (1992) found that as concentration increased in the American brewing industry, the failure rate of microbreweries decreased. However, the failure rate of large mass producers did not increase with market concentration. The resource partitioning model makes the following prediction:

Hypothesis 4a. Resource partitioning: As market concentration increases, the failure rate of large organizations increases and the failure rate of small organizations decreases.

Mass dependence, size-localized competition, and resource partitioning complement density-dependent explanations of population dynamics by highlighting two ways in which variation in organizational size creates competitive asymmetries that foster the evolution of concentrated size distributions common to older organizational populations. Mass dependence emphasizes that large organizations are dominant competitors and thus an especially important cause of competition. Size-localized competition and resource partitioning emphasize that size differences moderate interorganizational competition. Although the two roles large organizations play in aging populations appear contradictory, the prediction that larger organizations generate stronger competition is not incompatible with the idea that competition between large and small organizations is less intense than competition among large or

among small organizations. This is because increases in size-localized competition and resource partitioning are not incompatible with contemporaneous increases in the competitive strength of large organizations. Thus, size-localized competition and resource partitioning do not preclude the possibility that large organizations outcompete smaller rivals that operate in overlapping market segments.

Temporal Changes in the Basis of Competition

THE EVOLUTION OF ORGANIZATIONAL POPULATIONS: *r*-SELECTION, *K*-SELECTION, DIFFERENTIATION

The historical growth trajectories of diverse organizational populations appear to follow a common path: The number of organizations grows slowly initially, then increases rapidly to a peak. Once this peak is reached, there is a decline in the number of organizations and concentration increases (Hannan & Carroll 1992; Utterback & Suárez 1993). In their original statement of density-dependence theory, Brittain and Freeman (1980) identify several important changes in the basis of competition that accompany this common growth trajectory. According to Brittain and Freeman, organizational populations undergo a competitive transition from "*r*-selection" to "*K*-selection" as increasing population density alters the basis of competition from first-mover advantage to efficiency. They ground the distinction between these two bases of competition in the logistic growth functions underlying density-dependence theory in bioecology. A common logistic growth function is

$$\frac{dN}{dt} = rN[(K-N)/K]$$

where K is the carrying capacity of the population's environment, r is the natural growth rate of the population, N is the population density (i.e., the number of organizations in the population), and t is a time interval. In this equation, when population density is initially low, the natural growth term r dominates and organizations enter at a slow but exponentially increasing rate. However, as population density increases, the carrying capacity limit term K becomes dominant, and the rate of growth slows. Growth stops when population density is equal to the carrying capacity.

According to Brittain and Freeman (1980), in an emerging population, no organization or small group of organizations is dominant and new entrants are typically similar in size to established organizations. Competition is dominated by *r*-selection, which favors small organizations capable of moving quickly to exploit new resource opportunities in the resource-rich but dispersed and uncertain environments that characterize low-density conditions. Organizations compete by discovering new resource opportunities to exploit and by offering innovative goods and services. As the population continues to grow, its markets become connected, environmental uncertainty is reduced as demand becomes more predictable, and some organizations begin making broad, general appeals to all customers to expand their market shares. Along with the increased potential for competition that accompanies increasing population size (relative

to the abundance of resources), this begins to orient competition among the population's members toward cost and price reduction, favoring larger population members capable of achieving efficiency advantages.

When a population reaches the carrying capacity, the resources available to its members are exploited fully, and competitive pressures shift to *K*-selection, which favors larger organizations competing on the basis of efficiency. The economic and competitive advantages of the population's large members enable them to outcompete their smaller rivals, which are crowded out by the asymmetric competition. This "shakeout" decreases the number of organizations in the population, raises the level of market concentration, and creates a skewed or bimodal size distribution in which a few large organizations tend to dominate many smaller ones (Barnett & Amburgey 1990; Hannan & Freeman 1977; Ijiri & Simon 1977).

Ultimately, however, increasing market concentration forces large organizations to compete increasingly with one another for central markets capable of sustaining their large-scale operations (Carroll 1985). This specializes resource use to particular segments of the size distribution (Hannan & Freeman 1977) and creates pockets of demand that smaller, more specialized members of the population may be able to exploit without engaging in direct competition with the larger generalists (Barnett & Amburgey 1990; Carroll 1985). Thus, resource partitioning localizes the competitive effects of organizations — even large ones — to their particular segments of operations. Competition at carrying capacity also initiates a more general process of functional and territorial differentiation within the population as competition pushes entrepreneurs to seek out distinct functions in which they hold a competitive advantage (Hawley 1950). This creates organizational subgroupings that fulfill complementary roles in which they are dependent on, but noncompetitive with, each other (Baum & Singh 1994a, 1994b) and lowers the potential for competition by reducing the number of direct competitors each population member confronts (Baum & Mezias 1992; Delacroix, Swaminathan & Solt 1989).[2]

TEMPORAL HYPOTHESES

The foregoing account, which characterizes the evolution of organizational populations as a three-stage process of *r*-selection, *K*-selection, and differentiation, suggests that the strength of each of the four competition processes will change substantively over the course of an organizational population's history. First, if the shift to competition on the basis of efficiency (i.e., *K*-selection) increases the competitive strength of large organizations over their smaller rivals, then the strength of mass-dependent competition should increase over a population's history. Second, if the number of direct competitors (i.e., the number of other organizations that require the same resources) each organization faces within the population is reduced by resource partitioning and organizational differentiation, then density-dependent competition should weaken over a population's history. Third, if increased competition among large organizations for a population's central markets leaves smaller organizations to compete among themselves for more diverse, peripheral markets, then size-localized competition should intensify over a population's history. Fourth, and

finally, if large organizations focus increasingly on competing for central markets on the basis of efficiency, then the competitive effect of concentration on large organizations should increase over a population's history. These ideas suggest the four following hypotheses:

Hypothesis 1b. Density dependence: Density-dependent competition weakens over the course of a population's history.

Hypothesis 2b. Mass dependence: Mass-dependent competition strengthens over the course of a population's history.

Hypothesis 3b. Size-localized competition: Size-localized competition intensifies over the course of a population's history.

Hypothesis 4b. Resource partitioning: The competitive effect of increasing market concentration on large organizations increases over the course of a population's history.

Thus, while the influence of density-dependent competition is predicted to decline over a population's history, mass dependence, size-localized competition, and resource partitioning are predicted to play increasingly influential roles. If these size-based competitive processes are found to increase in strength over time, this would provide new insights into the propensity of older organizational populations to evolve concentrated size distributions.

Methods

DATA DESCRIPTION

The data used in this study include life history information on all 571 transient hotels that operated in Manhattan at any time between 1898 and 1990. Transient hotels are those catering to short-term visitors as opposed to residential hotels that serve long-term or permanent guests. Residential hotels were excluded from the sample. Four archival sources were used to construct these life histories. The *Hotel Red Book,* published annually since 1887, contains detailed information on the name, number of rooms, location, and room rates of hotels. It is the most comprehensive historical listing of Manhattan hotels in existence. The information contained in the *Red Book* was cross-referenced and supplemented using three additional archival sources: (1) the *Manhattan Classified Directory/Yellow Pages,* published since 1929; (2) the *Annual Directory of the Hotel Association of New York City,* published since 1940; and (3) the *Hotel and Travel Index,* published since 1951. Because detailed organizational data are missing for many hotels prior to 1898, the observation period for this study begins in 1898 even though the archival sources begin in 1887.

Between 1898 and 1990 the Manhattan hotel industry gradually transformed from one dominated by entrepreneurial, independent operators to one dominated by professionally managed hotels. After a period of slow growth in the decades preceding and following the turn of the century, the Manhattan hotel industry grew rapidly alongside the expansion of Manhattan during the "roaring twenties," reaching a maximum of 353 hotels in 1931. Since then, the industry has become more concentrated, a trend that accelerated after 1960 as smaller and medium-sized hotels were replaced by fewer and larger establish-

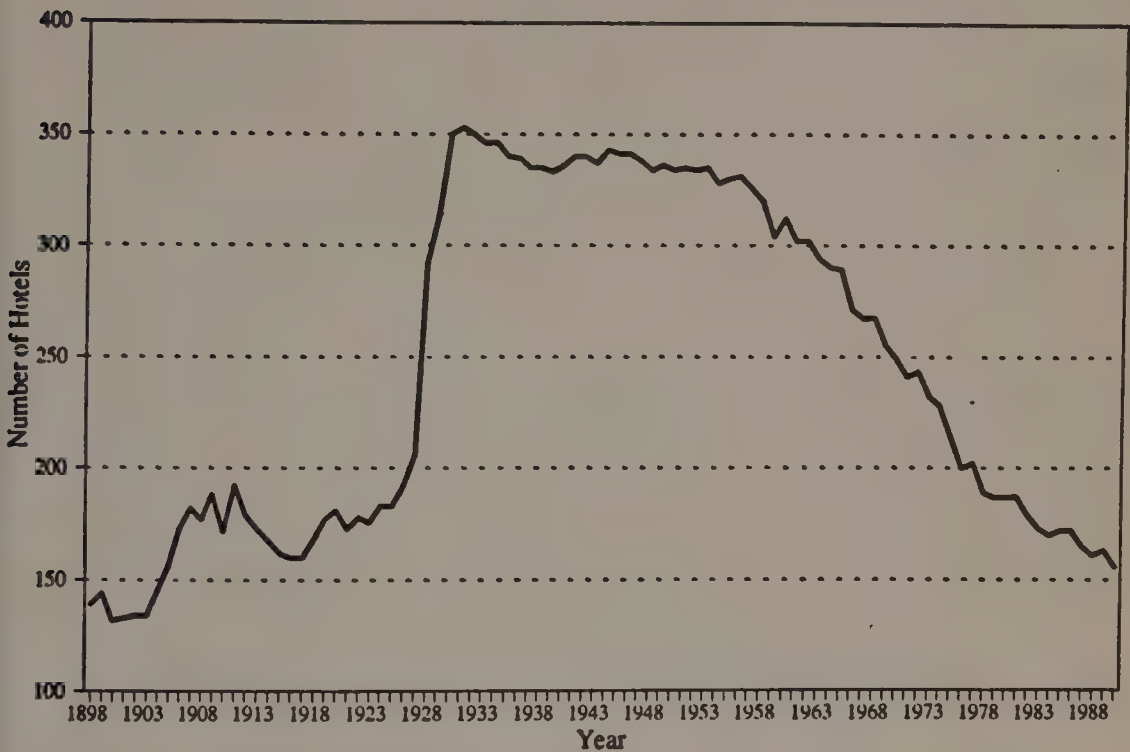
ments. The number of hotels in Manhattan in each year is shown in Figure 1.[3] Figure 2 illustrates how the average size of a Manhattan hotel, measured by the number of rooms, increased from fewer than 250 in 1898 to more than 400 in 1990.

During the study period, 438 transient hotels were founded in Manhattan. A hotel was defined to have been founded in the year it first appeared in any archival source. Furthermore, 339 (77.4%) of the hotels founded in Manhattan since 1898 had ceased operations by the end of 1990. Failure was defined as the cessation of hotel services for short-term visitors. Changes in name or ownership were not included as failures because the organization itself continued to provide transient-hotel services. The date of failure was defined as the year a hotel was permanently delisted from the *Red Book.* Whenever *Red Book* listings differed from those in the other archival sources, a hotel was defined to have failed in the first year it was permanently delisted from two or more of the archival sources.

In 1898, 133 of the hotels in the sample were already in operation; thus, the life histories for these hotels were left-censored (i.e., founded before the study period). To include as much of the data on hotels from the 1898-1990 period in the study as possible, I attempted to find founding dates for hotels existing in 1898. With available archival information, I was able to confirm founding dates for 112 (84.2%) left-censored hotels. Because their ages were not known, the 21 hotels with unknown founding dates could not be included in the analysis, although information on these hotels was included in the computation of population density, population mass, localized competition, and market concentration described below. Therefore, the final sample for the analysis included 550 hotels, of which 394 (71.6%) failed.

The competitive strengths of large hotels stem from several potential sources. Large hotels derive economies of scope from the ability to offer a wider range of services and to cater to a larger variety of clients (e.g., business travelers, corporate meetings, conferences, tourists, tour groups) simultaneously. This generalist capability provides shelter from environmental changes that affect demand in one client group but not in others. Large hotels can also exploit economies of scale in conference, dining, and recreational facilities that allow them to operate more efficiently and offer lower prices as a result of lower per-room costs than is possible for smaller hotels. Economies of scale are also realized in purchasing, reservation systems, advertising, marketing, and promotion. Large hotels are also better equipped to undertake major renovations by applying more resources to the task and maintaining the hotel's activities during periods of alteration by, for instance, closing several floors for renovation. Large hotels are also more "rate flexible," that is, capable of using predatory pricing to outcompete their smaller competitors for scarce clients. As the manager of one small Manhattan hotel put it, "If [Hotel X] put 100 of its 1,400 rooms on the market for $99, I'd be dead in the water. If I cut the rate on all my rooms, [Hotel X] wouldn't even notice, and I'd be out of business in no time." Rate flexibility also provides large hotels an advantage with corporate clients.

FIGURE 1: Number of Manhattan Hotels

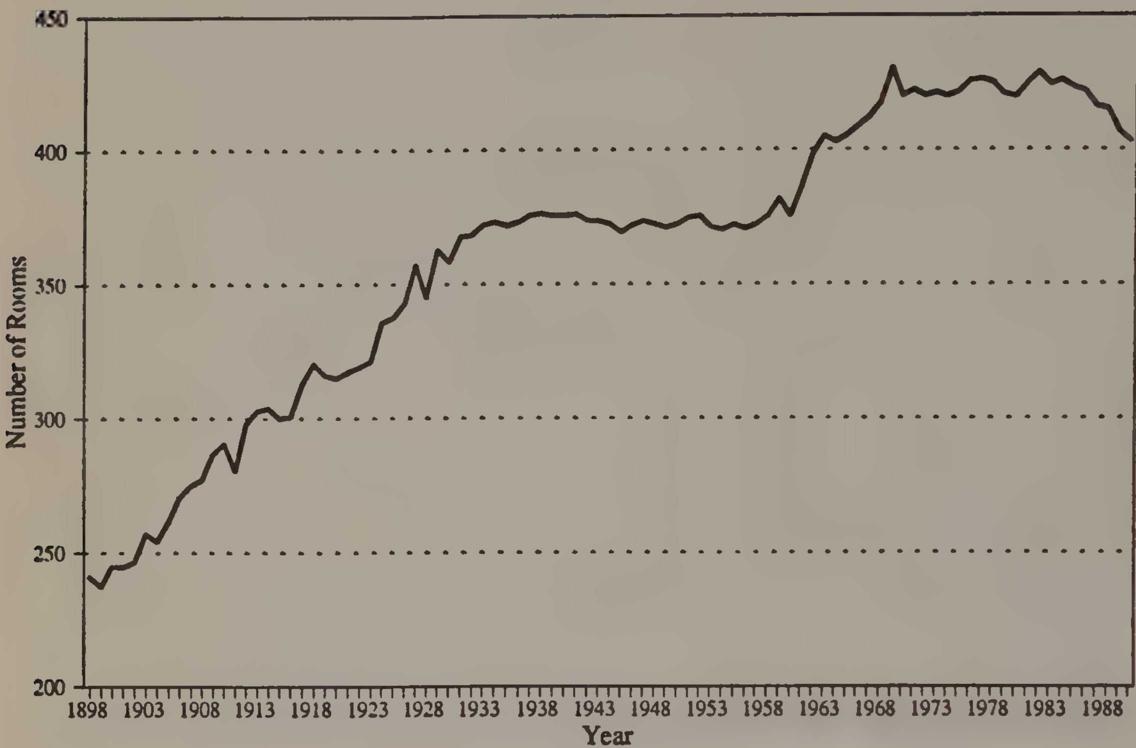


INDEPENDENT VARIABLES

Population density was measured as the total number of hotels existing at the start of each year. To allow for the curvilinear effect predicted by density-dependence theory, density was modeled as a quadratic function by including both density and density squared (divided by 1,000 for rescaling) in the analysis. Carroll and Hannan (1989) suggest that failure to incorporate data on the early period of a population's history may obscure the legitimating effects of population density. Consequently, because data on the Manhattan hotel industry are missing prior to 1898, the competitive effects of population density may be expected to dominate the density estimates. Density-dependent competition (hypothesis 1a) implies a positive effect of population density squared on the failure rate.

In order to capture the differential competitive strength of larger organizations, a measure of organizational size must capture total productive capacity, or plant size (Winter 1990). For hotels, the number of rooms operated represents this "productive capacity installed" (Winter 1990:288). Therefore, I derive all size-related measures based on the number of rooms a hotel operates at the start of each observation year, which is also the standard measure of size used in the hotel industry (Wyckoff & Sasser 1981).

FIGURE 2: Average Manhattan Hotel Size



Population mass was measured as the total number of rooms in all hotels (i.e., the total productive capacity of the industry) existing at the start of each year.[4] Following Barnett and Amburgey (1990), each hotel's number of rooms was subtracted from total mass, so the mass variable reflected the number of rooms operated by other hotels, and a natural logarithm transformation of mass was used. With density controlled, the effects of changes in the mass variable capture the effects of changes in the *average size* of other organizations (Barnett & Amburgey 1990:92). Therefore, mass-dependent competition (hypothesis 2a) requires a positive effect of population mass on the failure rate.

Size-localized competition was measured by comparing the size of a focal hotel, S_{it}, to the sizes of all other hotels in Manhattan, S_{jt}, $i \neq j$, within μ units of its own size at time t.[5] This is consistent with Hannan and Freeman's (1977) idea that competition is localized to particular segments of the organizational size distribution. The size differences between the focal hotel and the hotels within its competitive range were converted to a Euclidean distance, as follows:

$$D_{it}^{size \pm \mu} = \sqrt{\sum_{|S_{it}-S_{jt}|<\mu}^{\mu} (S_{it}-S_{jt})^2}. \tag{2}$$

$D_{it}^{size \pm \mu}$ increases with the average size difference between the focal hotel and other hotels within μ units, while the distances to hotels not within μ units of the focal hotel have no effect. Thus, large values for $D_{it}^{size \pm \mu}$ imply less potential size-localized competition. Therefore, size-localized competition (hypothesis 3a) presupposes a negative effect of $D_{it}^{size \pm \mu}$ on the failure rate.

The value for μ was set to the size of the focal hotel divided by two (i.e., $\mu = \pm S_i/2$) based on the earlier analysis of these data by Baum and Mezias (1992). This variable is called $D_{it}^{size/2}$ in the analysis.[6] This setting implies that a 100-room hotel competes with hotels ranging from 50 to 150 rooms, while a 1,000-room hotel competes with those from 500 to 1,500 rooms. Thus, $D_{it}^{size/2}$ limits the range of sizes over which hotels compete and takes into account that the competitive reach of large organizations is wider than that of small organizations (Winter 1990).

Last, *market concentration* was measured using the eight-firm concentration ratio, that is, the share of the total industry capacity accounted for by the eight largest hotels at the start of each year. The resource partitioning model predicts that increasing market concentration increases failure rates for large organizations but decreases failure rates for small organizations. Therefore, in addition to the main effect of market concentration, the effect of the interaction of market concentration and the size of a hotel was estimated. Support for resource partitioning (hypothesis 4a) requires a negative main effect for market concentration and a positive interaction between market concentration and size.

INDUSTRY AGE AND INTERACTION EFFECTS

Hypotheses 1b-4b predict variation in the effects of density, mass, size-localized competition, and market concentration over a population's history. To test these hypotheses, interaction terms were created to examine how the effects of the variables for the competitive processes changed over time. To do this, an *industry age* variable was constructed and interacted with the variables for the competitive processes. Industry age was set equal to the number of years since 1793, the year in which the City Hotel, the first modern hotel, was founded in Manhattan (Batterberry & Batterberry 1973).[7] Support for hypothesis 1b, which predicts a decline in the competitive effect of population density over time, requires a negative effect of the industry age × density squared interaction on the failure rate. Support for hypothesis 2b, which predicts an increase in the competitive effect of population mass increases over time, requires a positive effect of the industry age × mass interaction on the failure rate. Support for hypothesis 3b, which predicts an increase in size-localized competition over time, requires a negative effect of the industry age × $D_{it}^{size/2}$ interaction on the failure rate (recall that increases in $D_{it}^{size/2}$ indicate lower potential size-localized competition). Lastly, support for hypothesis 4b, which predicts an increase in the competitive effect of market concentration on large organizations over time, requires a positive effect of the industry age × size × market concentration interaction on the failure rate.

As is evident from Figure 1, the Manhattan hotel industry is well past its peak density. As described earlier, this complicates the legitimacy interpretation of the coefficient for the linear density term because late low density has no role

in density-dependence theory. This problem is corrected empirically by separating the effects of early low density from those of late low density. I do this by interacting the linear density term with a quadratic specification for the industry age variable, i.e., including separate terms for industry age and industry age squared (divided by 1,000 for rescaling). Because the squared term dominates the quadratic effect when industry age is high, the industry age interaction term captures the early low-density effect, and the industry age squared interaction captures the late low-density effect. Although density-dependence theory is commonly tested in populations that have evolved beyond their peak density (e.g., Hannan & Carroll 1992), effects of early and late low density are not separated in past research.[8]

CONTROL VARIABLES

To rule out plausible alternative explanations, I control for the effects of several organizational characteristics and variables influencing the environmental carrying capacity.

Organizational Variables

Age was defined as the number of years since the date of a hotel's founding. *Size* and *price* were measured, respectively, as the number of rooms operated by a hotel and the average daily room rate (in constant dollars) advertised by a hotel in each year of its existence. These variables were constructed using information contained in the archival sources described above. For a small number of hotels for which size or price data were unavailable for a given year, linear interpolation was used to determine the values. The logarithms of age, size, and price were used to reduce the variables' skewness. A left-censored dummy variable, coded 1 for hotels founded before 1898 and 0 otherwise, was also included to examine whether the hotels founded before 1898 had systematically different failure rates.[9]

Environmental Variables

The study also controlled for several factors influencing the environmental carrying capacity for transient-hotel services in Manhattan. The *potential demand* for hotel services was measured as the number of visitors (divided by 1,000,000 for rescaling) to New York City in the prior year. This variable includes arrivals by sea, rail, and air. Because the hotel industry is vulnerable to the state of the economy (Wyckoff & Sasser 1981), the annual *gross national product (GNP) growth rate* was included as a control.[10] The effects of the *number of foundings and failures* in the prior year on current failure rates were also controlled (Delacroix, Swaminathan & Solt 1989).

ANALYSIS

The failure rate of Manhattan hotels is estimated using $r(t)$, the instantaneous rate of failure. The hazard rate of a hotel failing is defined as:

$$r(t) = \lim_{\Delta t \to 0} [Pr(t, t+\Delta t|t)/\Delta t] \quad (3)$$

where $Pr(t, t+\Delta t \mid t)$ is the probability of failure in the interval t, $t+\Delta t$ given the hotel was still alive at time t. The failure rate was modeled using the following specification:

$$r(t) = \exp[\alpha X(\tau)],\ \tau_{(j-1)} < t \leq \tau_j \quad (4)$$

where $X(\tau)$ is a vector of covariate values at time τ, and α is a vector of coefficients. In this exponential model, transition rates are postulated to be log-linear functions of the variables in X. To include time variation in the covariates, a multiple-spells formulation was used. In this formulation of the model, each hotel's history is broken down into one-year spells in which the hotel is at risk of failing. Each spell is considered right-censored unless the hotel fails. This allows the time-varying independent variables to be updated annually. *RATE* (Tuma 1980) was used to estimate the vector of parameter estimates α by the method of maximum likelihood.

Results

Table 1 reports maximum-likelihood estimates for the analysis of Manhattan hotel failure rates. Model 1 provides a baseline model of competitive processes that includes a quadratic specification of industry age and the organizational and environmental control variables. Model 1 provides mixed support for the ecological models of competition. Coefficients for the quadratic specification of population density are both significant but have signs opposite in direction to those predicted by density-dependence theory. In contrast to hypothesis 1a, this implies that competition among hotels was weakest when population density was highest and strongest when population density was lowest. The mass dependence model (hypothesis 2a) is, however, supported by the significant, positive coefficient for population mass. With population density controlled, this means that increases in the average size of other hotels had competitive effects that increased the failure rate for smaller hotels. The coefficient for $D_{it}^{size/2}$ is significant and negative as predicted by the size-localized competition model (hypothesis 3a). This indicates that hotels with smaller average Euclidean distances from others within their competitive size range exhibited higher failure rates. In other words, hotels with more similar-sized competitors exhibited significantly higher failure rates. However, the resource partitioning model (hypothesis 4a), which predicts that the failure rate of large organizations increases with increases in market concentration, is not supported. Together, the significant, positive coefficient for market concentration and the significant, negative estimate for its interaction with size indicate that large size-buffered hotels from the hazardous effects of market concentration.

Model 2 introduces the interactions between industry age and population density. Adding these interaction terms improves the fit of the model significantly ($\Delta\chi^2 = 17.70$, df $= 3$, $p < .05$). In model 2, the coefficients for the quadratic population density specification are both significant and positive. The positive population density squared coefficient supports the density-dependent competi-

tion prediction (hypothesis 1a). In addition, the coefficient for the industry age × density squared interaction is significant and negative, supporting hypothesis 1b. Taken together, these estimates indicate that the failure rate increased at an increasing rate with population density but that the competitive effect of increasing population density weakened over the hotel industry's history. The estimates for the linear density term's interactions with quadratic specification for industry age are also noteworthy. The industry age × density interaction is

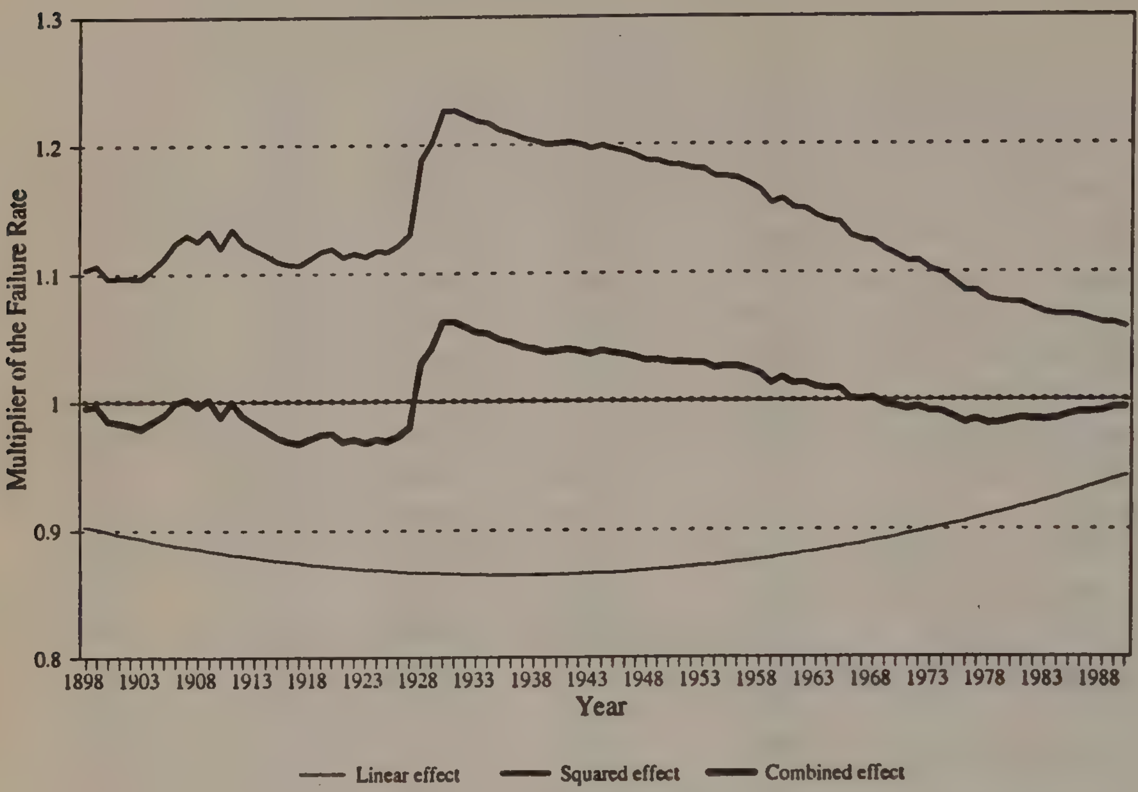
significant and negative and the industry age squared × density interaction is significant and positive. Combined with the positive linear effect of population density, the interaction effects indicate that density increases lowered the failure rate in early low-density conditions but raised the failure rate in late low-density conditions.

Figure 3 illustrates the temporal variation in the population-density and population-density-squared effects graphically. This figure gives multipliers that show the effects of adding one hotel to population density in each year. In the figure, a multiplier of greater than one indicates that the failure rate increases relative to the estimate based on the actual density in that year by a factor equal

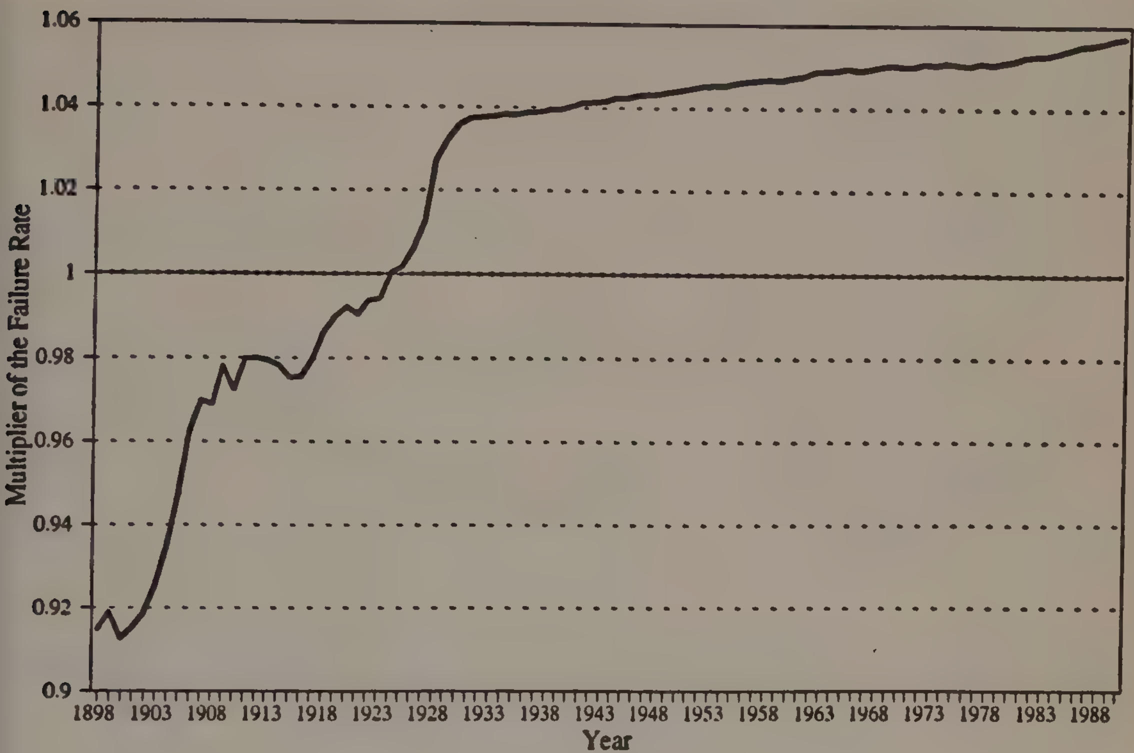
FIGURE 3: Population Density Effects (Model 2)



to the multiplier. A multiplier of less than one indicates that the failure rate decreases by such an amount. As the figure shows, the multiplier for the squared (i.e., competitive) effect of adding one hotel hovers around 1.1 from 1898 to 1927, jumps to over 1.12 in 1931 along with the industry's rapid 1928-31 expansion, and declines steadily thereafter as predicted by hypothesis 1b. By comparison, the multiplier for the linear effect of adding one hotel to the population declines initially from .9 to .86 but then increases to .94 by the end of the observation period. The relatively small initial decline may result, as noted above, from missing data on the population's early history, obscuring the legitimating effects of population density (Carroll & Hannan 1989). Nevertheless, consistent with the density-dependent legitimation argument (Hannan & Carroll 1992), the multiplier for the overall effect shows that density increases in early low-density conditions lowered failure rates in the Manhattan hotel industry. Thus, only after incorporating time variation in the effects of population density and population density squared are density-dependent processes of legitimation and competition observed clearly.

Model 3 introduces the industry time clock × mass interaction. Adding this interaction term again improves the fit of the model significantly ($\Delta\chi^2 = 10.47$, df = 1, $p < .05$). In model 3, supporting hypothesis 2b, the coefficient for the industry age × mass interaction is significant and positive. Moreover, in contrast to the estimates for population mass in models 1 and 2, the estimate for the

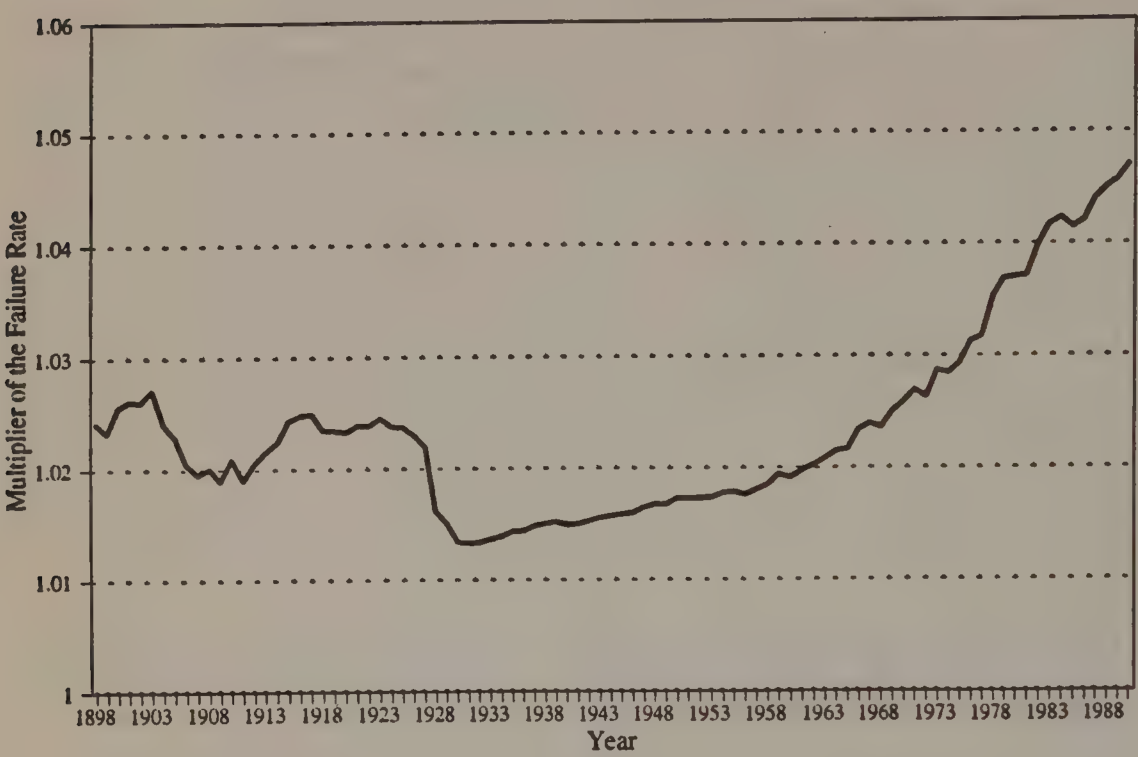
FIGURE 4: Population Mass Effects (Model 3)



main effect of mass is significant and negative in model 3. In combination, with population density controlled, these estimates for the main and time-varying effects of population mass indicate that, early in the observation period, increases in the average size of other hotels had mutualistic effects that lowered the failure rate. However, over the observation period, increases in the average size of other hotels had increasingly competitive effects that increased the failure rate of smaller hotels. Thus, unless time variation is considered, the mass estimates fail to distinguish the early mutualistic and later competitive effects of large hotels. This temporal variation in the mass effect is illustrated in Figure 4, which gives a multiplier that shows the effect of adding 500 rooms to population mass in each year. As Figure 4 shows, the multiplier for adding 500 rooms to the population increases rapidly from 0.92 in 1898 to 1.04 in 1930, increasing more moderately thereafter. Notably, the multiplier is less than 1 before 1925, indicating that increases in population mass had a mutualistic effect that lowered the failure rate early in the observation period. Thus, mass-dependent competition played its role in the evolution of the industry later in the observation period as large hotels gained competitive strength, displacing smaller hotels and decreasing the number of hotels.

Introducing the industry age × $D_{it}^{size/2}$ interaction in model 4 improves the fit of the model significantly again ($\Delta\chi^2 = 4.00$, df = 1, $p < .05$). In contrast to previous models, the estimate for $D_{it}^{size/2}$ is not significant in model 4. However,

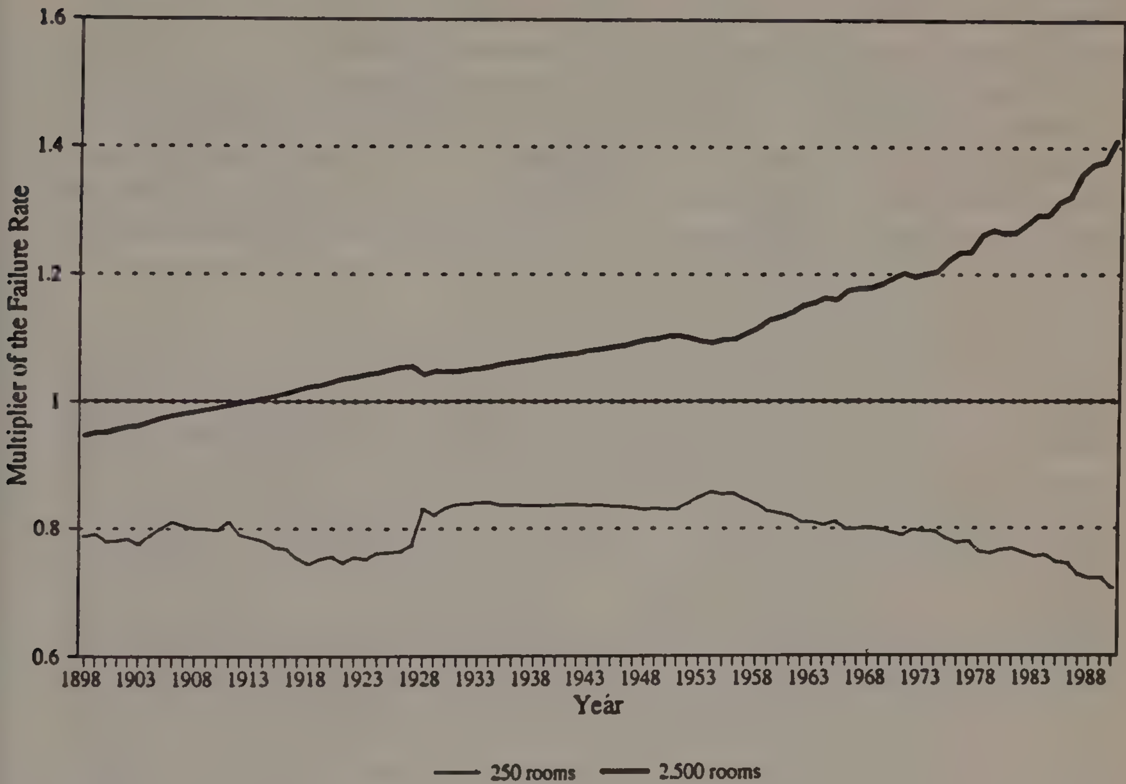
FIGURE 5: Size-Localized Effects (Model 4)



the industry age × $D_{it}^{size/2}$ interaction is significant and negative. Given that the main effect of $D_{it}^{size/2}$ on the failure rate is not significant, the interaction effect suggests that the intensity of size-localized competition was initially low but increased over the course of the Manhattan hotel industry's history, supporting hypothesis 3b. Figure 5 illustrates this temporal variation in the effect of size-localized competition graphically. This figure gives a multiplier that shows the effect of reducing $D_{it}^{size/2}$ by the average Euclidean distance to another hotel in each year. As Figure 5 shows, the multiplier for increasing size-localized competition by one hotel of average size similarity varies between 1.02 and 1.03 from 1898 to 1928, drops with the population's rapid growth, and then increases continuously, reaching nearly 1.05 by 1990. Thus, like mass-dependent competition, the importance of size-localized competition increased over the course of the industry's history.

Finally, model 5 introduces the industry age × size × market concentration interaction.[11] The two additional two-way interactions included in the model are required to obtain an unbiased estimate for the three-way interaction of interest (Cohen & Cohen 1983). Again, adding these interaction terms improves the fit of the model significantly ($\Delta\chi^2 = 20.02$, df = 3, $p < .05$). Supporting hypothesis 4b, the coefficient for the industry age × size × market concentration interaction is significant and positive. However, contrary to resource partitioning theory, the main effect of market concentration remains significant and positive and the size

FIGURE 6: Market Concentration Effects (Model 5)



× market concentration interaction remains significant and negative. The industry age × market concentration interaction is also significant and negative. The complex implications of these interactions are depicted graphically in Figure 6. This figure gives multipliers that show how increasing market concentration in each year by 10% affects the failure rate for hotels with 250 and 2,500 rooms. Three features of Figure 6 are noteworthy. First, the multiplier is always higher for the 2,500-room hotel than for the 250-room hotel. Second, the multiplier for the 250-room hotel is always less than 1, indicating that increases in concentration always lower its failure rate. Third, the multiplier for the 2,500-room hotel increases over the observation period from 0.95 to 1.4, while the multiplier for the 250-room hotel falls from 0.8 to 0.7. Thus, the positive industry age × size × market concentration interaction dominates the negative size × market concentration interaction, resulting in an overall effect that is consistent with the predictions of resource partitioning theory (hypothesis 4a) and hypothesis 4b.

The organizational and environmental control variables also had several significant influences on hotel failure rates. In contrast to the commonly observed age-dependent decline in organizational failure rates, the significant positive estimate for age indicates that hotel failure rates increased with age. Thus, a hotel is an expensive physical asset that, if not properly maintained, may be subject to obsolescence (Baum & Mezias 1992). However, consistent with

prior work, hotel failure rates did exhibit negative size dependence. Failure rates were also lower among luxury hotels than among economy hotels. The estimate for the left-censored dummy variable is insignificant in all models. Thus, although hotels founded before the observation period were already in a sense "survivors," they did not exhibit a survival advantage.

Among the environmental factors, increases in potential demand (i.e., the number of visitors to New York City) and the GNP growth rate both lowered the failure rate. The failure rate also declined as resources released by hotel failures in the prior year enhanced the viability of surviving hotels (Delacroix, Swaminathan & Solt 1989) but was unrelated to the number of prior foundings.

Discussion and Conclusion

This article began by noting that density-dependence theory alone cannot account for the widely observed pattern of proliferation and concentration in organizational populations. Although density dependence provides an explanation for the initial proliferation to an equilibrium level, it does not explain the subsequent concentration because it does not permit asymmetric competition that allows some population members to become dominant. Prompted by this basic limitation of density-dependence theory and research, I attempted to contribute to an explanation for this evolutionary tendency of organizational populations in two ways. First, I combined density dependence with complementary models of ecological competition that incorporate size-based competitive asymmetries among the members of a population. Second, based on the original statement of density-dependence theory in organizational ecology (Brittain & Freeman 1980), I advanced hypotheses that predict changes in the strengths of competitive processes over the course of a population's history. The findings show how incorporating time variation in multiple competitive processes can provide a more detailed understanding of the competitive dynamics and evolution of an organizational population.

My analysis of the Manhattan hotel industry demonstrates that hotels of different sizes generate and experience different strengths of competition and that the strengths of density- and size-based competitive processes change over time. Although there is evidence that four distinct competitive processes influenced the Manhattan hotel industry simultaneously, I draw attention to the results establishing the changing basis of competition, which provide new insights into the propensity of older organizational populations to become concentrated. Supporting the idea that, over time, resource partitioning and organizational differentiation reduce the number of direct competitors each organization faces within a population, the competitive effect of population density weakened over the observation period (hypothesis 1b). However, consistent with the idea that as competition on the basis of efficiency intensifies over time, larger organizations become stronger competitors than their smaller rivals (Brittain & Freeman 1980) and mass-dependent competition intensifies (hypothesis 2b). The results also support the prediction that similarly sized organizations become more intense competitors over time (hypothesis 3b). This is compatible with the idea that as resource partitioning proceeds, competition

among large organizations to occupy central markets intensifies, leaving smaller organizations to compete with each other for more specialized resource opportunities. Lastly, and also consistent with the prediction that large organizations focus increasingly on competing with each other as resource partitioning proceeds, the harmful effect of market concentration on the survival of large organizations increased over time (hypothesis 4b).

Overall, the findings extend empirical evidence linking competitive processes to population dynamics by demonstrating that, while density dependence was vital to the initial proliferation of the Manhattan hotel industry, size-based competitive asymmetries became increasingly important over time, helping to account for the industry's later decline in numbers and concentration. Thus, our understanding of the evolution of the industry is enhanced by combining ideas from four models of ecological competition and by permitting the effects of competitive processes specified by each model to vary over the industry's history instead of restricting the effects of these variables to be time-invariant (Isaac & Griffin 1989).

Although the basic findings of this study the were broadly consistent with theoretical expectations, the mutualistic effect of the presence of large hotels early in the observation period provides an interesting exception. Several factors may account for this early mutualistic effect of large hotels. While large hotels may generally have been stronger competitors, their political and economic strength may also have facilitated the early growth of the industry. Manhattan's early "grand hotels" were a new phenomenon, unlike the inns or taverns typical of the time. Visitors to the city told wondrous stories of Manhattan's grand hotels; they were cities within a city, completely self-contained "Palaces of the People, where any man, with a few extra dollars to spend, could live like a king, at least for a few days" (Batterberry & Batterberry 1973:80). Thus, the initial emergence of large hotels may have contributed to the institutional legitimacy of the hotel industry in Manhattan and may also have helped stabilize the resource environment by helping to attract a regular flow of business and tourist travelers to the New York City area. Small hotels may have benefited from the presence of large hotels in a more direct way if proximity to large hotels was a indication to travelers of the desirability of their location. Moreover, smaller and newly established hotels may have been able to improve their survival chances by drawing on the strengths of the industry's early large hotels, for example, by servicing their overflow clients.

As the industry grew, and the basis of competition shifted toward an emphasis on cost and efficiency, the increasing competitive strength of the industry's large members made it increasingly difficult for smaller participants to compete effectively, overwhelming the mutualistic effects. However, smaller hotels were somewhat sheltered from their larger rivals as competition among them to occupy central markets intensified, leaving smaller hotels to compete among themselves for peripheral resources. Thus, large hotels may have played an important role both in the initial expansion of the industry and also in its later decline in size as a smaller number of larger hotels displaced the industry's smaller participants.

Several implications and directions for future research follow from the results of this study. First, as with any other single-industry study, the results

may reflect industry-specific factors. Future replications of this study in other populations are needed to help establish the generalizability and broader significance of the findings. For example, although this study provides evidence that the basis of competition changes in the Manhattan hotel industry, future research is needed to examine predictions regarding the conditions that give rise to these changes. Are there industries in which the basis of competition changes in different ways or not at all? One interesting possibility is Barnett and Amburgey's (1990) suggestion that the competitive reach of large organizations is affected by the heterogeneity of the population's niche. In heterogeneous niches the competitive reach of a large organization is predicted to be localized to its segment(s) of the niche, increasing the potential for size-localized competition. By comparison, in homogeneous niches the competitive reach of large organizations is extensive, increasing the potential for mass-dependent competition. In moderately heterogeneous niches, such as the Manhattan hotel industry, the potential for both mass-dependent and size-localized competition exists. Research examining the effects of niche heterogeneity may therefore improve our understanding of factors underlying changes in the basis of competition.

Second, while this research concentrates on variations in the intensity of competitive relationships that depend on differences in organizational size, theory in organizational ecology suggests that similarity more generally (e.g., similarity in targeted clients, goods and services produced, and technologies employed) is a primary determinant of the intensity of competition between organizations (e.g., Aldrich 1979; Baum & Singh 1994a, 1994b; Hannan & Freeman 1977, 1989; McPherson 1983).[12] Among hotels, for example, resource requirements, and thus the intensity of competition, vary not only with similarity in size, but also with similarity in price and location (Baum & Mezias 1992; Lant & Baum 1995). Traditionally, hotels have positioned themselves in one of three service-level categories oriented toward well-defined market segments: luxury, midprice, or economy. This results in patterns of resource use that are specialized to regions of the price distribution, intensifying competition between similarly priced hotels. Hotels also compete more intensely within relatively local market areas defined by their proximity to points of tourist interest or business activity from which the demand for hotel services is derived. Thus, competition is most intense between establishments of similar class or market position within relatively compact and well-defined geographic areas or hotel districts (Baum & Mezias 1992; Lant & Baum 1995). Research also shows that competitive intensity varies with similarity in the characteristics of affiliated members of voluntary associations (McPherson 1983, 1990) and similarity in the ages of children enrolled in day-care centers (Baum & Singh 1994a, 1994b). Future research that considers organizational differentiation more broadly may therefore improve our understanding of factors influencing competitive intensity and evolution of organizational populations.

Third, although this study has drawn some initial links among ecological models of competition by examining how their strengths vary over an organizational population's history, clearly the relationships among of these models need to be explored more fully. Ecological theory can be enriched by integrating further ideas from multiple models of population dynamics (Singh 1993). For

example, this study focused on how changes in the basis of competition over a population's history influence patterns of competition among organizations of different sizes. However, Brittain and Freeman's (1980) density-dependence model and Carroll's (1985) resource partitioning model both have broader implications for the changing mix and relative success of strategies within a population of organizations over time. As described earlier, Carroll focuses on specialist and generalist strategies and Brittain and Freeman focus on *r*- and *K*-strategists. While specialists and *r*-strategists are predicted to thrive in emergent population, generalists and *K*-strategists are predicted to dominate older populations. However, size is only one organizational feature related to the differences between specialists and generalists and *r*- and *K*-strategists. Notably, these ecological categories encompass concepts of market breadth and market aggressiveness, which are central to classifications of competitive strategy in the strategic management literature (Romanelli 1989). Consequently, future studies that consider organizational differences in strategic orientation may provide a bridge between research in organizational ecology and the field of strategic management, which is also interested in explaining why some strategies lead to competitive superiority while others do not.

Finally, this study brings into question past research that tests for density dependence in populations that have evolved beyond their peak density. Systematic changes in the sizes and strategies of organizations over a population's history suggest that the adequacy of population density as a proxy for competition is diminished over a population's history. Therefore, I modeled density dependence together with three size-based models of competition and permitted time variation in the density-squared effect to account for these changes and reduce specification bias due to unobserved heterogeneity in the density estimates (Tuma & Hannan 1984). Furthermore, when density is equally low early and late in a population's history, the legitimacy account of the coefficient for the linear density term is unclear because late low density has no meaning in density-dependence theory. Therefore, since population density is equally low early and late in the Manhattan hotel industry's history (see Figure 1), I separated the effects of early and late low-density conditions empirically. Notably, after accounting for the effects of size-based competition and permitting time variation in density-dependence effects, density-dependent predictions of legitimation and competition were supported. This increases my confidence in the density-dependence model, but it also raises questions about the veracity of past research findings — both supportive and unsupportive. However, it is not the purpose of this article to either criticize or defend density-dependence theory. It is to challenge the inertia in organizational ecology research on competition and industry evolution by pointing out some key limitations of density dependence, while, at the same time, showing that these limitations can be overcome and new insights gained by adopting a broader, multitheoretical approach that combines density dependence with other well-established ecological models of competition.

This research is the first to examine the changing basis of competition in organizational populations. The findings of this study demonstrate the potential significance of such changes for a basic evolutionary property of organizational populations: the tendency of older populations to become concentrated. Given

the evidence linking temporal changes in the basis of competition to population evolution, I believe future research that attends to the historical as well as diverse ecological processes of organizational populations will provide new insights into organizational evolution.

Notes

1. In more technical terms, when tested in populations that have evolved beyond their peak density, population density estimates suffer from specification bias due to unobserved heterogeneity (Tuma & Hannan 1984). This occurs when one or more independent variables that influence the dependent variable are omitted from the analysis.

2. Similar arguments are made in models of spatial competition in economics. These models predict that competition among products in a bounded characteristics space leads to product differentiation, which leads, in turn, to a decrease in the intensity of product competition (e.g., Swann 1985, 1990).

3. Although the period of rapid growth in the late 1920s coincides roughly with the addition of the *Yellow Pages* data source, it is not attributable to the addition of this source. This growth, which accompanied the rapid expansion of Manhattan during this time, is reflected in the *Red Book* as well.

4. This is a departure from Barnett and Amburgey's (1990) measure of population mass, the total number of telephones. However, as Winter (1990) points out, Barnett and Amburgey's variable is arguably a measure of the demand served by other organizations rather than their capacity.

5. The assumption that a focal hotel competes only with other hotels within a certain range of its own size is consistent with the earlier analysis of these data by Baum and Mezias (1992).

6. Baum and Mezias (1992:597-98) discuss the robustness of $D_{it}^{size \pm \mu}$ to changes in the value of μ. They also discuss and model the effects of localized competition in terms of hotels' geographic location and price (pp. 589-91). Adding these forms of localized competition to the models reported below does not change the substantive findings.

7. This starting date was used for industry age for comparability. Results reported below do not differ substantively if the industry age clock is started in the first observation year.

8. Hannan and Carroll (1995) use a similar approach. However, they do not include main effects for industry age or industry age squared in their interaction models. This biases their estimates, making interpretation of their findings problematic (Cohen & Cohen 1983).

9. Although membership in a hotel chain may influence the survival of individual hotels, chain membership data are not available in the *Red Book* and so could not be controlled in this study.

10. These two variables were constructed using information contained in the *Historical Statistics of the United States, Colonial Times to 1970* (U.S. Department of Commerce, Bureau of the Census, 1975), *Historical Abstracts of the United States* (U.S. Department of Commerce, Bureau of the Census, 1970-1990), and *Port of New York and New Jersey Authority* annual reports (1930-1990).

11. The implications of models 2-4 in Figures 3-6 are not altered substantively using estimates from model 5.

12. Similar views are taken in strategic (e.g., Porter 1980) and economic (e.g., Scherer & Ross 1990; Tirole 1988) theories of competition.

Interracial Contact and Black Racial Attitudes: The Contact Hypothesis and Selectivity Bias*

DANIEL A. POWERS, *University of Texas at Austin*
CHRISTOPHER G. ELLISON, *University of Texas at Austin*

Abstract

One of the most serious criticisms of research on the contact hypothesis is the contention that selection bias operates to promote interaction between whites and blacks who are already relatively unprejudiced toward one another. Accordingly, attempts to infer the effect of interracial contact on racial attitudes must recognize and correct for this potential source of bias. Endogenous switching regression models are used to estimate the effect of close interracial friendship on selected racial attitude variables while accounting for possible selectivity bias. Each model implies a distinct assumption about the process generating interracial contact and racial attitudes. Using data from the National Survey of Black Americans, we find no evidence of sample selection bias in estimating the effect of close interracial contact on black racial attitudes. Therefore, we cannot reject the conventional models used in research on the contact hypothesis that treat interracial contact as an exogenous variable affecting racial attitudes. However, our results show the usefulness of a switching regressions approach to reveal the contingent nature of the contact hypothesis.

For at least four decades, social scientists have debated the value of the contact hypothesis for the study of racial and ethnic relations (Allport 1954; Jackman & Crane 1986; Sigelman & Welch 1993; Stephan 1987). This hypothesis holds that contact, particularly close and sustained contact, with members of different racial and ethnic groups promotes positive, tolerant attitudes toward those groups. Proponents of the contact hypothesis maintain that interracial contact provides direct information — frequently accurate and favorable information — on the values, lifestyles, and experiences of other groups. This positive firsthand information may be generalized into a positive perception of the group(s) as a whole, thus permitting individuals to counter unfavorable racial and ethnic stereotypes. Commentators have also presented more conditional versions of the

* *Data were made available by the Interuniversity Consortium for Political and Social Research, Ann Arbor. We are grateful to Arthur Sakamoto and the anonymous reviewers for helpful comments on an earlier version. However, the authors are responsible for the analyses and interpretations presented here. contact hypothesis, suggesting that contact may promote positive racial and ethnic attitudes only under ideal conditions — for instance, when the contact involves persons of equal status, when it takes place under cooperative conditions, and when it enjoys the active support of powerful authorities (Allport 1954; Desforges et al. 1991).

To date, research on the contact hypothesis has been plagued by three critical limitations. First, most empirical investigations over the years have been conducted in specific institutional contexts (e.g., interracial housing projects, desegregated schools, the military) or in laboratories (Brown & Albee 1966; Butler & Wilson 1978; Desforges et al. 1991; Wilner, Walkley & Cook 1955). However, most interracial contact does not occur in these specialized, highly monitored settings. Thus, while these studies have contributed to our understanding of intergroup relations, until recently they have left open the question of whether interracial contact results in positive racial attitudes in the general population. Three recent studies using general population samples have reached divergent conclusions about the usefulness of the contact hypothesis for the study of race relations (Ellison & Powers 1994; Jackman & Crane 1986; Sigelman & Welch 1993).

Second, research on the contact hypothesis has focused primarily on white racial attitudes, giving short shrift to the views of African Americans. The handful of exceptions to this general pattern over the years have yielded discrepant findings (Ford 1973; McDowell 1971; Robinson & Preston 1976; Works 1961). Because many African Americans are forced to encounter whites frequently in public settings, due to the demographic imbalance between blacks and whites, and because such contact often takes place under competitive and even hostile circumstances, it appears that casual interracial contact is not necessarily associated with positive racial attitudes among African Americans. However, more intimate interracial contacts, such as close white friendships, seem to promote positive racial attitudes among African Americans (Ellison & Powers 1994; Sigelman & Welch 1993). Given mounting evidence that the contact hypothesis works differently for blacks than for whites, additional research on the implications of interracial contact for the racial attitudes of African Americans seems warranted.

Third, several recent studies have raised important questions on the causal assumptions of the contact hypothesis (Jackman & Crane 1986; Sigelman & Welch 1993). For instance, some have suggested that the positive association between contact and positive attitudes reported in cross-sectional studies may reflect primarily a selection effect: Initially tolerant attitudes may lead individuals to engage in, or even to seek out, interracial contacts, while less tolerant persons eschew such contacts. If this interpretation is accurate, then research on the contact hypothesis for the past four decades has been fundamentally misguided, and further inquiry on the consequences of interracial contact holds little promise for social scientists or policymakers. The urgency of this question has been underscored by Sigelman and Welch (1993), who concluded their recent analysis by noting that "our findings pinpoint the issue [of causal order] as a live one, the resolution of which should be a priority focus in future research on blacks' and whites' racial attitudes" (793).

This study contributes to the literature on the contact hypothesis in several ways. In the absence of large-scale panel data on interracial contacts and racial attitudes, we propose endogenous switching regression models to examine issues of causality and selectivity that have dogged recent research on the contact hypothesis. After elaborating the rationale for this approach, we then test several sets of hypotheses concerning black racial attitudes, using data from a large ($N = 2{,}107$), nationally representative cross section of African Americans.

The Selection Problem in Research on the Contact Hypothesis

One of the most serious criticisms of research on the contact hypothesis is the contention that selection bias operates to promote interaction between whites and blacks who are already relatively unprejudiced toward one another. Most statistical models of the relationship between contact and attitudes assume that contact is an independent (exogenous) variable influencing racial attitudes. This implies that, net of observed covariates, contact and attitudes are statistically independent. However, it may be that initially tolerant attitudes lead persons to engage in or even seek out interracial contact.

Models based on other assumptions about the process generating interracial contact and racial attitudes may yield different estimates of the effects of key variables. If contact is viewed as an exogenous variable in a model predicting racial attitudes, the estimated effect of contact is simply the difference between the average attitude measure for those who have experienced contact and those who have not. However, if observed attitude differences between those who have experienced contact and those who have not are due to predispositions toward racial tolerance rather than interracial contact per se, then the effect of interracial contact is no longer simply a difference in average attitude measures. The estimated effect of contact and other key variables in regression models of racial attitudes will be inconsistent as a result of a selection bias that sorts people nonrandomly into situations of contact with members of other racial and ethnic groups.

A selection model interpretation offers a more fruitful approach for the analysis of interracial contact and racial attitudes by altering the causal sequence surrounding attitude change implicit in most contact research. In such models, common unmeasured factors would affect both the probability of engaging in interracial contact and the strength of particular racial attitudes.

Data and Measures

Data from the National Survey of Black Americans (NSBA) (Jackson, Tucker & Gurin 1987) are used to test models alternative to the contact hypothesis. The NSBA is a survey conducted by the Survey Research Center (SRC) at the University of Michigan during 1979-80. The sampling and interview procedures, which are described elsewhere in more detail (see Jackson 1991), yielded a sample of 2,107 adults.

DEPENDENT VARIABLES

In this article we seek to explain the observed association between interracial contact and racial attitudes while controlling for observed covariates and taking account of possible selection bias. We take a closer look at racial attitude variables measuring (1) the amount of skepticism that blacks feel toward whites, and (2) the degree of blacks' opposition toward interracial dating. These variables are standard indicators that have appeared in the literature on racial attitudes (see Schuman & Hatchett 1974; Schuman, Steeh & Bobo 1988).

First, we consider blacks' *skepticism about the motivations of whites.* This information is obtained from responses to the question; "On the whole, do you think most White people want to see blacks get a better break, or do they want to keep blacks down, or don't they care one way or another?" Approximately 22% of NSBA respondents supplied the most favorable response, while an additional 35.9% answered that whites are indifferent to the situation of blacks. The remaining 42.1% felt that whites seek to oppress blacks.

Second, we consider blacks' *disapproval of interracial dating,* measured in terms of the strength of the respondent's agreement with the following two statements: (1) Black men should not date white women; and (2) Black women should not date white men ($r = .80$). These items range from "strongly disagree" (coded 1) to "strongly agree" (coded 4). Our indicator is the mean response to these two items, which range from 1 to 4 with a mean of 2.145 and a standard deviation of 1.41.

To assess the effect of interracial contact on racial attitudes, we assume that blacks who have close white friends occupy a distinct position or status from blacks who do not. The availability of *close white friends* is measured by the following dichotomous item: "Do you know any White person who you think of as a good friend — that is, someone to whom you can say what you really think?" Approximately 57% of the NSBA respondents reported having at least one such white friend.

INDEPENDENT VARIABLES

We control for the influence of background factors that are established predictors of racial attitudes (see Demo & Hughes 1990; Ellison 1991): *age* (in years); *education* (8-point summary scale); gender (1 = *female*); *family income* (17-point summary scale); *urban* vs. rural residence (1 = resident of self-representing urban area); *South* (1 = resident of southern state, according to the U.S. Bureau of the Census classification).

In addition to these control measures, we include two additional racial contact variables that influence attitudes and interracial friendship formation. *Childhood contact* refers to casual contact with whites that occurred earlier in life. This is measured in terms of the racial composition of the respondent's elementary school, junior high school, high school, college, and childhood neighborhood. *Adult contact* refers to the level of casual interracial contact experienced by the respondent at the time of the NSBA interview. This is measured in terms of the interracial composition of the respondent's current neighborhood, church or place of worship, and workplace. The responses on

these items range from "all blacks" (coded 1) to "almost all whites" (coded 5). Our measure of each contact variable is the mean score on the corresponding set of items.

Although it is reasonable to expect that, other things being equal, persons who are immersed in interracial settings regularly will actually experience more interpersonal contact with individuals of other racial and ethnic backgrounds, we acknowledge that these indicators cannot measure actual contact precisely. Nevertheless, these indicators are identical to those used in several recent studies of racial attitudes among whites and blacks (e.g., Ellison & Powers 1994; Sigelman & Welch 1993). Thus, our use of these measures maximizes continuity with previous research in this area.

ENDOGENOUS SWITCHING REGRESSION MODELS FOR CAUSAL EFFECTS

The selection problem of contact research is closely related to the problem of estimating the effects of statuses, social positions, and treatment effects from sample surveys (Blalock 1964; Winship & Mare 1992). White friendship may be regarded as a treatment variable representing two groups, "no white friends" (coded 0) and "white friends" (coded 1), into which blacks are assigned, possibly nonrandomly. The extent to which assignment to each of these groups is nonrandom can be investigated with endogenous switching models (Mare & Winship 1988; Winship & Mare 1992).[1] As Winship and Mare (1992) note, these models are "suitable for assessing the effects of a social classification . . . on a consequence of membership in this classification" (338).

Following the conventional notation for switching regression models (see Mare & Winship 1988; Winship & Mare 1992), we assume that NSBA respondents are drawn from a population of blacks, each of whom is characterized by values for the variables y_1, y_0, z, x. Each person is characterized by two hypothetical attitudinal outcomes: y_1 denotes the attitudinal outcome that would have been observed in the black population among those having close white friends; and y_0 denotes the outcome that would have resulted among those *not* having close white friends. Let $z = 1$ if a respondent reported having white friends, and 0 otherwise. Because either attitudinal outcome y_1 or attitudinal outcome y_0 is realized, it follows that y_1 is latent (or missing) when y_0 is observed ($z = 0$), and y_0 is latent (or missing) when y_1 is observed ($z = 1$). The *realized* outcome $y = zy_1 + (1 - z)y_0$.[2]

Attitudinal outcomes (y_1 and y_0) and white friendship status (z) depend on a collection of predetermined exogenous sociodemographic and control covariates x_j ($j = 1, \dots J$), where $x_1 = 1$ for all individuals to allow for constant terms. With no loss of generality, y_1, y_0, and z may depend on common or unique subsets of x_j; some covariates may affect racial attitudes, others may influence the formation of close friendships with whites, and some may affect both attitudes and friendship formation. Following Mare and Winship (1988), the system of equations for the ith individual can be written as

$$y_{1i} = \sum_j \beta_{1j} x_{ji} + \epsilon_{1i} \qquad \text{if } z_i = 1 \tag{1a}$$

$$y_{0i} = \sum_j \beta_{0j} x_{ji} + \epsilon_{0i} \quad \text{if } z_i = 0 \tag{1b}$$

$$z_i = 1 \text{ if } \sum_j \gamma_j x_{ji} + \eta_1 y_{1i} + \eta_0 y_{0i} + \nu_i > 0 \tag{1c}$$
$$= 0 \text{ otherwise}$$

where β_{kj} ($k = 0,1$) denotes the regression effect of x_j on the attitude measures, γ_j denotes the corresponding effect of x_j on white friendship, η_1 and η_0 are the effects of racial attitudes on white friendships, and $x_{1i} = 1$ for all observations to allow for equation intercepts. It is worth noting that in restricted versions of this model some x_j may be excluded from certain equations above and some effects on attitudinal outcomes may be the same for persons in either white friendship position.

We assume that errors are independently distributed, trivariate normal with a mean of zero and variances of σ_0, σ_1, and 1, υ is uncorrelated (conditional on x) with the remaining equation errors (ε_1 and ε_0), and all x_j are uncorrelated with the equation disturbances. The covariance σ_{01} is fixed at zero. This term is not identified, as each person realizes either y_1 or y_0.

A reduced form of the z equation is useful in the subsequent applications.

$$z_i = \sum_j \pi_j x_{ji} + \epsilon_{zi} \tag{2}$$

where

$$\pi_j = \gamma_j + \eta_1 \beta_{1j} + \eta_0 \beta_{0j}, \text{ and } \epsilon_{zi} = \eta_1 \epsilon_{1i} + \eta_0 \epsilon_{0i} + \nu_i.$$

In general, the error term of the reduced form equation, ε_z, will be correlated with ε_1 and ε_0.[3]

We make use of continuous and dichotomous measures of racial attitudes. For the skepticism measures, we focus separately on the most positive and most negative racial attitudes. We noted earlier that approximately 22% of the NSBA sample expressed the most positive attitude that "Whites wanted to see Blacks get a better break," whereas approximately 35.9% of the NSBA sample expressed the negative racial attitude that "Whites want to keep Blacks down."

Each response from the skepticism measure can be treated as a dichotomous dependent variable. Those respondents who express another attitude than the positive are neutral or have a negative attitude. Similarly, those respondents expressing an attitude differing from the most negative attitude are either neutral or have positive attitudes. In the case of the positive racial attitude, $y_1 = 1$ if a black person with close white friends expressed the attitude that whites seek to give blacks a break, and zero otherwise. Likewise, $y_0 = 1$ if a black person without close white friends believed that whites seek to give blacks a break, and zero otherwise. Similar expressions obtain for the negative racial attitude. Each equation in the system above would be estimated as a probit regression subject to the standard normalization, $\sigma_1 = \sigma_0 = 1$ with error correlations ρ_{1z} and ρ_{0z}.

The interracial dating measure is treated as continuous. Here, y_1 represents the degree of disapproval of interracial dating expressed by a black American with close white friends, and y_0 is the same attitude of a black American without close white friends. The two attitude equations would be estimated as OLS regressions with error covariances σ_{1z} and σ_{0z}.

Models and Their Implications

Several competing models can be estimated, each of which tests assumptions implicit in contact research by placing restrictions on the parameters in equations 1 and 2. These restrictions are outlined in more detail in the Appendix.

MODEL 1: THE GENERAL MODEL

The general model imposes the fewest restrictions. The magnitudes and signs of the estimated error covariances (correlations) provide information about the degree and direction of nonrandom selection into one or another of the white friendship statuses. For example, $\sigma_{1z}>0$ (or $\rho_{1z}>0$, if equations 1a and 1b are probit equations) provides evidence of positive selection of persons into the "white friends" position, whereas σ_{1z} (ρ_{1z}) <0 implies negative selection into the "white friends" status. Similarly, σ_{0z} (ρ_{0z}) <0 provides evidence of positive selection of persons into the "no close white friends" position. Thus, net of observed covariates, these conditions imply that (conditional on x) blacks are sorted nonrandomly into positions of close friendship with whites.

If these conditions hold, then models that attempt to account for the observed association of interracial friendship and racial attitudes and also fail to control for nonrandom allocation of individuals into friendship statuses will yield inconsistent estimates of the effect of interracial friendship on racial attitudes.

MODEL 2: THE ASCRIPTION MODEL

The ascription model (Mare & Winship 1988) describes the situation in which persons are selected into statuses only on the basis of their observed characteristics. Under this model racial attitudes would not affect white friendship formation after controlling for covariates. If this prediction holds, then each equation estimated separately for the appropriate subsample would yield consistent estimates of covariate effects. This model is tested as a restricted version of the general model by setting the equation error covariances (correlations) to zero.

This model is consistent with the standard model of contact research; however, the effects of independent variables depend on whether the respondent reports having white friends.

MODEL 3: THE STRUCTURAL SHIFT MODEL OF HECKMAN

The two previous models allow covariate effects on racial attitudes to vary according to whether a person has white friends. This means not only that average sentiments are shifted by having close white friends, but that changes in the covariate values would exert nonproportional changes in sentiments when a person has close white friends. An alternative model proposed by Heckman (1978) allows only the *shift* in sentiments rather than the *change* in sentiments induced by differences in the effects of covariates. This model

implies that covariate effects are the same regardless of friendship status. The model is a restricted version of the general model obtained by constraining the regression slopes and error covariances (correlations) to be equal across the attitude equations, although equation intercepts are allowed to vary.

Heckman's model is consistent with the standard model of contact research (see, e.g., Ellison & Powers 1994; Sigelman & Welch 1993), but it allows for the possibility that interracial contact is an endogenous variable in a model predicting racial attitudes.

MODEL 4: THE STANDARD CONTACT MODEL

The exogenous contact model is the model invoked by most past research on the contact hypothesis. It can be cast as a restricted version of Heckman's model. The model is obtained by adding the constraint that equation covariances (correlations) are zero. That is, contact is assumed to be an exogenous determinant of racial attitudes.

In sum, the general model (model 1) and Heckman's structural shift model (model 3) run counter to the assumptions implicit in contact research. Both models incorporate parameters that permit an assessment of the magnitude and direction of selection bias. Model 3, however, constrains all covariate effects and error covariances or correlations to be equal regardless of whether a respondent has close white friends. Model 2 may be viewed as a weak version of model 4 (the standard contact model), obtained by including the full set of interactions of all independent variables with the close white friends variable. Stronger versions of model 2 would constitute a class of intermediate models incorporating a subset of interaction effects. The models may be summarized as follows:

		Interaction by Friendship Status	
		Yes	No
Sample Selection by Friendship Status	Yes	General (1)	Heckman (3)
	No	Ascription (2)	Standard (4)

MODEL SPECIFICATION

We impose various exclusion restrictions to assist in identifying the structural models and to ease the task of estimating the three-equation system. Specifically, we include certain variables in the selection equation (z) that are not included in the structural equations (y_0 and y_1). Substantively, these instrumental variables should tap general interpersonal attributes that facilitate friendship formation yet should be unrelated (or weakly related) to the formation of specific racial attitudes. Unlike most large national survey projects, the NSBA contains several interviewer assessments of the respondent and of aspects of the interview itself. For example, the interviewer was asked to rate the demeanor of the respondent at the time of the interview.[4] Two such interviewer assessments

are of interest in this study. Interviewers rated respondents on one continuum ranging from friendly (1) to hostile (7), and another continuum ranging from open (1) to suspicious (7). We use the average of these two items ($r = .72$) as an index of *interpersonal congeniality*. We include this post hoc interviewer evaluation as a predictor of close white friendships. This measure has the advantage of tapping the interpersonal qualities of the respondent and being a strong predictor of the formation of friendships with whites while not predicting racial attitudes. We also assume that gender affects friendship formation but has a negligible effect on skepticism. However, gender is assumed to influence attitudes toward interracial dating.

To summarize, the probability of forming friendships with whites is assumed to depend on age, urban residence, southern residence, education, income, childhood and adult interracial contact, interpersonal congeniality, and gender. Further, we assume that racial attitudes depend on all these factors except interpersonal congeniality and gender. Interracial dating attitudes are assumed to depend on all these factors except interpersonal congeniality.[5]

Results

Tables 1 and 2 present selected results from models of racial attitudes involving skepticism of whites' motives. Looking at the general model in Table 1, we find no evidence of nonrandom selection into white friendship status (for positive racial sentiments). The estimates of ρ_{1z} and ρ_{0z} are close to zero and statistically insignificant. Therefore, the basic exogenous contact model cannot be rejected on the basis of the data from the NSBA. Moreover, the ascription model with unconstrained slopes provides no evidence of the presence of interaction effects with friendship status. The findings in Table 2 for negative racial attitudes indicate that the exogenous selection model cannot be rejected, and the contact model fits as well as any of the less constrained models.

Table 3 presents selected results from the models of interracial dating attitudes. The estimates of σ_{1z} and σ_{0z} are close to zero and not statistically significant in both the general model and the structural shift model. Again, we find no evidence of selection bias. However, a likelihood chi-square test of the ascription model against the contact model shows that the former provides a better fit to the data ($\chi^2_9 = 37.4$).

Table 4 presents estimates from the general model of skepticism of the motives of whites. The effect of interracial contact (close white friends) is estimated as $\sum_j \hat{\beta}_{1j}\bar{x}_{1j} - \sum_j \hat{\beta}_{0j}\bar{x}_{0j}$. The effect of close white friends on positive racial attitudes is .686 while the effect on negative racial attitudes is -.338. Substantively, this implies that having white friends increases the probability of expressing optimism about the motivations of whites by .19 and decreases the chances of expressing pessimism about the motivations of whites by .13.[6]

Although the general model fits the data as well as the more parsimonious contact model, several differential effects of friendship status bear mentioning. First, the effect of income on *positive* attitudes among respondents with white friends is larger than the corresponding effect in the sample without white friends. On average, among those with white friends, a $1,500 increase in 1978

individual income leads to a .011 decrease in the probability of expressing the attitude that whites want to give blacks a break.[7] However, the *difference* in the income effect between persons with white friends and those without white friends is not statistically significant ($p = .38$), perhaps because of the small number of NSBA respondents without white friends who reported positive racial attitudes ($N = 89$). Second, income has a positive effect on the probability of expressing *negative* attitudes. Among respondents without close white friends, this effect is marginally significant ($p = .07$).[8] In the sample of NSBA respondents without white friends, a $1,500 increase in income leads to a .006 increase in the chances of expressing the attitude that whites want to keep blacks down. The magnitudes of these marginal effects suggest that income has, at best, a modest impact on skepticism attitudes.

Third, it is also noteworthy that among African Americans with white friends, age increases the likelihood of viewing the motivations of whites in a positive light. Each 10-year increase in age increases the chances of believing that whites want to give blacks a break by .039. The corresponding increase in probability for those without white friends is .030. This difference in age effects between persons with and without white friends is not statistically significant at conventional levels ($p = .11$). Our concluding section offers a more detailed substantive interpretation of these empirical patterns.

Table 5 shows how net effects would be estimated in the standard contact model. Overall, these effects are similar in magnitude to the estimates from the general model in Table 4 for NSBA respondents who reported having close

white friends. The *effect* of close white friends in the contact model is estimated as the difference between the corresponding constant terms, or .649 for the positive racial attitude compared to -.341 for the negative racial attitude. (Alternatively, these effects could be estimated by including a term for close white friends in a single probit equation.) These effects imply that having white friends increases the probability of expressing optimism about the motivations of whites by .13 and decreases the probability of expressing pessimism about the motivations of whites by a comparable amount.

Table 6 compares estimates from the general model and the contact model of opposition toward interracial dating. The effect of close white friends on opposition to interracial dating is estimated as the difference in the average opposition to interracial dating between blacks who have close white friends and blacks who do not, or -.166. For the contact model, this effect is estimated by the difference between the constant terms, or -.148. The switching regressions approach permits a more complete assessment of covariate effects than the standard exogenous contact model. For example, the effect of education on opposition to interracial dating is three times as large among NSBA respondents with close white friends and is five times its standard error. These differences in the effects of education are statistically significant at conventional levels ($p = .001$).

We also find that casual adult interracial contact is associated with low levels of opposition to interracial dating among African Americans who have white friends. However, casual contact has no bearing on these attitudes among

blacks without white friends. This difference between respondents with and without white friends is statistically significant at the .03 level. Thus, it seems that both the quantity and the variety of interracial contacts (intimate and casual) are important in eroding interracial suspicion and hostility.

The switching regressions approach offers some advantages over the conventional approach in revealing the differential effects of education and casual adult interracial contact on opposition to dating attitudes between those with and those without white friends. The net effect of allowing for differential effects can be seen by comparing the standard contact model to the ascription model. The likelihood ratio chi-square, or -2 times the difference between the log-likelihoods of the standard contact model and the ascription model in Table 3, is 37.4 with 9 degrees of freedom ($p < .005$). Therefore, the ascription model, or a less constrained version of the standard contact model, is more appropriate for explaining opposition toward interracial dating.

Summary and Conclusions

The contact hypothesis has been the subject of research in racial and ethnic relations for at least four decades. Although some recent investigators have found apparent support for the core claims of the contact hypothesis using data from large cross-sectional samples, they also raise the possibility that the empirical association between interracial contacts and positive racial attitudes

could result from unobserved selection processes. That is, preexisting positive racial attitudes may incline some individuals to form and sustain interracial friendships, while preexisting negative attitudes may discourage other persons from pursuing such interracial contacts. If the pivotal assumption that interracial contact is an exogenous determinant of racial attitudes is false, then future research on the contact hypothesis will be of little value.

One frequently mentioned strategy for examining this assumption of exogeneity would use longitudinal data (Jackman & Crane 1986; Sigelman & Welch 1993). However, a number of methodologists caution that longitudinal data may be unsuitable for resolving thorny issues of causality (Clogg 1986).[9] Moreover, to the best of our knowledge, such data are unavailable, especially for African Americans.

Therefore, we have taken a different tack, using endogenous switching regression models to analyze cross-sectional data from the National Survey of Black Americans (NSBA). Four competing models were elaborated and estimated: (1) the general selection model; (2) the ascription model; (3) Heckman's (1978) structural shift model; and (4) the standard contact model, which, like the ascription model, assumes that interracial contact is an exogenous determinant of racial attitudes. These analyses showed nothing that would lead us to reject the exogeneity assumption. There is no evidence that the observed association between interracial contact and racial attitudes is an artifact of unobserved selection processes, and hence there is no reason to reject the findings of previous research conducted within the contact tradition. It appears that while casual interracial contacts have little bearing on attitudes, close interracial friendships may provide African Americans with direct information about the values, life-styles, behaviors, and experiences of their white counterparts, enabling many to counter negative images and stereotypes of whites.

We emphasize that these methods may be generalized to a number of substantive areas of sociological inquiry in addition to the one considered here. Although we caution against the blind application of selection models in general, there are many situations in which methods to investigate selectivity bias are warranted. Researchers wanting to estimate treatment effects from nonexperimental data often face a missing data problem that makes causal inference subject to selection bias. The application of endogenous switching models to these situations would permit a more rigorous assessment of alternative assumptions about the processes that influence socioeconomic outcomes and sample selection probabilities.

Of course, this study has focused exclusively on African Americans and has examined only two of the many possible racial attitudes. Thus, further research is needed to test the exogeneity assumption for white Americans and for other attitudinal outcomes. Nevertheless, given these reassuring findings and the acrimonious contemporary racial climate, it is important to clarify those structural and institutional arrangements (e.g., in neighborhoods, schools, and workplaces) that promote the development of interracial friendships.

One ancillary benefit of our investigation of possible selection effects is that it reveals the contingent nature of the contact hypothesis. Research on the contact hypothesis has largely neglected selection effects, save for occasional attention to the role of various immediate situational factors — e.g., the views

of authorities on intergroup relations, the relative status of the parties engaging in contact, the cooperative or competitive nature of the contact — in moderating the relationship between contact and intergroup attitudes. Recent investigations using large secondary data sets have focused exclusively on estimating the main net effects of interracial contact on racial attitudes (e.g., Jackman & Crane 1986; Sigelman & Welch 1993), without considering the possibility that the nature and consequences might relate to one's age/cohort, socioeconomic status, or other aspects of social location.

Several intriguing patterns in our study suggest that this has been a nontrivial oversight. For instance, earlier research (Ellison & Powers 1994) reported an inverse association between educational attainment and black opposition to interracial dating, a finding that is consistent with most studies of white attitudes. However, our respecification of this relationship indicates that this relationship exists only among African Americans with close white friends; among their counterparts who lack these interracial bonds, there is no meaningful association between education and attitudes toward interracial dating (see Table 6). This difference in the estimated effects of education is large and statistically significant ($p < .001$).

This pattern is especially interesting because educational attainment is often considered a more accurate indicator of black middle-class standing than income (e.g., Smith 1989). However, a more modest pattern also emerges in the relationship between income and African American perceptions of whites' motives (Table 4). Among African Americans with close white friends, income reduces the likelihood that individuals will hold positive views of whites' motives but does not increase the likelihood that individuals will hold negative views. In contrast, among those persons lacking close interracial friendships, income is positively associated with the likelihood of believing that most whites "want to keep blacks down."

Although this latter difference does not reach conventional levels of statistical significance, perhaps because of the small number of NSBA respondents without white friends who reported positive perceptions of whites' motives, in both cases access to close interracial friendships seems to condition the link between socioeconomic status and African American racial attitudes. Our findings dovetail with several strands of recent research depicting the frustration and rage of many upwardly mobile blacks, who continue to combat various types of racial discrimination despite marked improvement in their economic resources and occupational standing. For instance, Feagin's (1991) interviews in several cities document the diverse covert and overt episodes of discrimination confronted in the course of daily life by well-educated, professional African Americans: rejection by lenders and realtors, poor service in restaurants and other business establishments, police harassment, and verbal epithets from white strangers, among many other examples. On the basis of interviews with leading executives, academics, and other upwardly mobile African Americans, Cose (1993) identifies twelve "demons," or recurring race-related stressors that have shattered expectations and reduced the quality of life for many middle- and upper-class African Americans. These items range from low expectations and lack of respect from white colleagues on the job to exclusion from white-dominated clubs and other social settings.

Taken together with evidence of "glass-ceiling" effects and other structural barriers to black middle-class success (e.g., Collins 1983, 1993; Geschwender & Carroll-Seguin 1990; Landry 1987), the research of Feagin, Cose, and others underscores the growing sense of frustration and relative deprivation among many upwardly mobile African Americans. Our findings suggest that the trust and openness of interracial friendships may be especially important in shaping the racial attitudes of members of the black middle class, reducing the likelihood that unpleasant encounters with interpersonal or institutional racism will be generalized into a negative portrait of whites as a group.

Two additional contingent patterns also merit brief discussion. First, among blacks with white friends, the casual contact that likely follows from involvement in racially integrated settings (e.g., workplaces, neighborhoods) appears to reduce opposition to interracial dating, an especially intimate form of interracial contact (Table 6). Among those blacks who lack close white friendships, on the other hand, we find no association between adult contact and attitudes toward interracial dating. This difference in the estimated effects of adult interracial contact is statistically significant ($p < .03$). It is interesting that this pattern does not emerge in analyses of perceptions of whites' motives in issues related to the welfare of African Americans (Table 4).

This finding raises the possibility that persons who acquire positive information about whites through close personal friendships may interpret subsequent exchanges and interactions with whites in a more positive light and may assimilate the information gained through these more casual contacts into a relatively benign image of whites as a group. However, due to the demographic imbalance between blacks and whites, most African Americans are forced to interact with whites from time to time regardless of their preferences for interracial contact (e.g., Butler & Wilson 1978). Thus, for persons who lack positive sources of information to counter widespread negative perceptions of whites, the level of casual contact has little bearing on attitudes toward interracial dating.

Our analyses have also turned up limited evidence of age/cohort differences in the implications of interracial friendships for African American attitudes. Among blacks with white friends, older respondents tend to report favorable views of whites' motives (Table 4), while among blacks who lack close interracial friendships, age is unrelated to this attitudinal outcome. There are two plausible interpretations of this pattern. On the one hand, by virtue of their age, older African Americans have had longer to cultivate and nurture close friendships with whites. It is reasonable to suspect that interracial friendships of longer duration may provide more candid and revealing information about whites than those of more recent origin. On the other hand, this pattern may constitute modest evidence of a cohort effect. Older African Americans may have vivid recollections of earlier periods in which race relations were more acrimonious and racial barriers were more rigid, and they may also recall the significant interracial cooperation of the civil-rights era. Given this historical frame of reference, older African Americans may more readily generalize positive experiences with whites gained via personal friendships into a relatively favorable image of whites as a group. Possible age/cohort differences in the effects of interracial contact merit further research.

This study has augmented our understanding of the causes, processes, and consequences of interracial contact by (1) reaffirming the key causal assumption underlying the contact hypothesis, (2) providing new information about the relationship between interracial contact and the racial attitudes of African Americans, and (3) demonstrating that the effects of such contact vary according to aspects of social location (e.g., socioeconomic status, age/cohort). Additional research is needed to explore these contingent relationships in a broader array of racial attitudes and to investigate the existence of such contingent patterns among white Americans as well. Finally, the NSBA data were collected from 1979 to 1980, and substantial changes in the U.S. political economy and racial climate over the last 15 years may have altered the patterns identified in this study. Although, to the best of our knowledge, more recent data on interracial contact and racial attitudes in large samples of African Americans are exceedingly rare, the collection and analysis of such data should be an important priority for the future.

APPENDIX

Each competing model imposes a different set of restrictions on equation slope parameters β_{0j}, β_{1j}, γ_j, $(j = 1,k)$ η_0 and η_1, or equivalently, equation covariances σ_{1z} and σ_{0z} or correlations ρ_{1z} and ρ_{0z}.

THE GENERAL MODEL

The general model imposes the fewest restrictions on parameters. The only assumption is that σ_{10} or $\rho_{10} = 0$, whereas σ_{1z}, σ_{0z}, ρ_{1z}, and ρ_{0z} are free to vary.

THE ASCRIPTION MODEL

The ascription model is tested as a restricted version of the general model by setting $\sigma_{1z} = \sigma_{0z} = 0$ or $\rho_{1z} = \rho_{0z} = 0$.

THE STRUCTURAL SHIFT MODEL OF HECKMAN

Heckman's structural shift model is a restricted version of the general model obtained by setting $\beta_{0j} = \beta_{1j}$ $(j > 1)$ and $\sigma_{1z} = \sigma_{0z}$ or $\rho_{1z} = \rho_{0z}$.

THE STANDARD CONTACT MODEL

The exogenous selection contact model can be cast as a restricted version of Heckman's model. In addition to the constraint that the $\beta_{0j} = \beta_{1j}$ $(j > 1)$, this model is obtained by setting $\eta_0 = \eta_1 = 0$, or equivalently, $\sigma_{1z} = \rho_{1z} = \sigma_{0z} = \rho_{0z} = 0$.

All these models can be estimated in HotzTran (Avery & Hotz 1985). The ascription model and standard contact model can be estimated using OLS and probit regressions when the observed attitudinal outcome is continuous or binary. The structural shift model can be estimated using bivariate probit regressions.

Notes

1. Mare and Winship (1988) discuss the situation in which assignment to position is made by a decision maker (e.g., the placement of a student in a particular school track level is made by teachers, school administrators, and parents). Our situation is one in which individuals self-select into different positions.

2. This is a latent variable approach insofar as y_1 and y_0 may be thought of as blacks' propensity to exhibit positive (or negative) perceptions of whites' motivations, whereas z may be thought of as blacks' propensity to form friendships with whites.

3. Identification of this model hinges on the assumption of a trivariate normal error distribution. The realizations of the latent dependent variables in equations 1a and 1b may be continuous, binary, or censored outcomes, corresponding to OLS, probit or tobit equations respectively (Powers 1993).

4. All NSBA interviews were conducted by African Americans.

5. A number of alternative models were examined that included different exclusion restrictions or no exclusion restrictions. The estimates we report are robust to alternative model specifications.

6. The marginal effect of close white friendship on the probability of expressing a particular racial attitude is given by $\Phi(\sum_j \hat{\beta}_{1j}\bar{x}_{1j}) - \Phi(\sum_j \hat{\beta}_{0j}\bar{x}_{0j})$, where $\Phi(.)$ denotes the standard cumulative normal distribution function (cdf).

7. The marginal effect of a change in x_k on the probability that $y = 1$ is given by $\partial P(y = 1|x_k)/\partial x_k = \phi(\sum x_k\hat{\beta}_k)\hat{\beta}_k$, where $\phi(.)$ denotes the standard normal probability density function (pdf). Individual income is constructed as a 17-point summary scale. A unit change in the scale represents an average change of $1,500 in 1978 dollars.

8. All reported p values are for two-tailed tests.

9. Although many authors concur that the relationship between contact and attitudes is bidirectional, most assume that contact causes attitudes, not the reverse. Whether causality can be assessed in the absence of longitudinal data is questionable. The question of the exogeneity of the effect of interracial contact would remain an issue regardless of the sampling plan.

Exploring the Determinants of Adult Black Identity: Context and Process*

DAVID HARRIS, *Northwestern University*

Abstract

This article assesses the impact of childhood interracial contact and parental socialization on adult black identity. The investigation goes beyond previous work by testing hypotheses about the process by which these two factors operate, as well as differentiating between black and person-of-color identities. Evidence is found to support claims that interracial contact in childhood weakens adult feelings of closeness to other blacks. Mixed support for the impact of parental socialization emerges once a more precise definition of identity is employed. With respect to process, insufficient support is found for the claim that childhood factors affect closeness through black culture and outgroup orientation. The article concludes by outlining arguments regarding the merits of black identity and calling for research to help resolve this controversy.

This article addresses concerns that accompany integration by examining the impact of childhood interracial contact and socialization messages on adult black identity.[1] While this topic has previously been the subject of several studies (e.g., Broman, Jackson & Neighbors 1989; Demo & Hughes 1990; Jackson, McCullough & Gurin 1988), the present analysis represents an extension of this research in two important ways. First, the article contributes to the literature on black identity by introducing a refinement of the concept of identity. The closeness measure used in other work is modified to differentiate black identity from feelings of closeness to other people of color. Second, both direct and indirect effects of childhood factors on adult black identity are examined. Too often previous work has identified important determinants of identity but failed to empirically address process. However, if we are to expand our knowledge of racial identity, the importance of understanding process is certainly on par with that of assessing the significance of potential determinants.

* *The data used in this article were made available by the Inter-University Consortium for Political and Social Research. The data for the National Survey of Black Americans, 1979-1980, were originally collected by James S. Jackson and Gerald Gurin. This research was supported by funding from the National Science Foundation. I wish to thank Roberto Fernandez, Nicola Beisel, Aldon Morris, Christopher Jencks, and Michael Thornton for their helpful comments on earlier drafts of this article. Each helped greatly to improve the work presented here, but are of course not responsible for its content. Data and Methods

THE SAMPLE

Data for this project are drawn from the National Survey of Black Americans (NSBA; Jackson & Gurin 1987). Collected by researchers at the University of Michigan, this data set is the result of interviews conducted between 1979 and 1980 with 2,107 respondents. The age range of respondents is from 17 to 101. This national household probability survey was administered face to face by black interviewers. For the most part, the NSBA is representative of the national black population enumerated in the 1980 census. Exceptions are a slight overrepresentation of females and older blacks and a small underrepresentation of southerners.

Variables

DEPENDENT VARIABLE

In this article, black identity is represented by feelings of closeness to other blacks. This conceptualization of identity conflicts with two findings from the literature. First, black identity is a multidimensional construct. Demo and Hughes (1990) and Phinney (1990) report feelings of closeness, separatist notions, and group evaluation as distinct components of black identity. The present concentration on only one of these dimensions is not meant as a dismissal of the other two, but rather is an attempt to emphasize the facet of black identity that most closely resembles classic definitions of group identity. The closeness measure employed here captures the crucial characteristics of group identity as "we" (Cooley 1902) and "a shared feeling of peoplehood" (Gordon 1964: 24) better than do constructs of separatism or group evaluation.

Second, several scholars have shown the strength of black identity to depend on the segment of the black population chosen as the reference group (e.g., Allen, Dawson & Brown 1989; DuBois [1899] 1973). While such attention to the intricacies of intraracial identity are certainly important, there is also a great need to understand blacks' identification with all other blacks. Many issues affecting blacks are not specific to class, age, or gender. Most people who see a black person on the street are unable to surmise much about the individual other than his or her race (Feagin 1991). As many scholars have noted, blackness is like a uniform. Especially in the company of strangers, it has the tendency to supersede an individual's other characteristics (Blauner 1972; Gordon 1964; Park 1950). For this reason the present analysis does not divide black identity into feelings of closeness to various intraracial reference groups.

Operationalizing black identity as closeness to other blacks is nothing new. In fact, it is a definition selected by many scholars who have worked with the NSBA. Where the construction of identity in this article differs from previous work is in its effort to purge black identity of its component that represents a sense of community with other nonwhites. Blauner (1972) maintains that nonwhite Americans think of themselves as a group in opposition to whites, rather than as an array of distinct ethnicities. He attributes this conception of

society to the civil-rights struggles of the 1960s. For many blacks, Hispanics, Native Americans, and Asian Americans, the lesson has been learned that minority groups must work together if they are ever to secure a position of equality with whites. This merger of interests has been accompanied by the appearance of a new group in society — people of color. It is for this reason that all equations in which closeness to blacks is the dependent variable also include a control for closeness to other minorities. Without such a control, it is unclear whether observed effects are on one's black or person-of-color identities.

Feelings of Closeness to Other Blacks

Respondents were asked how close they felt in their ideas and feelings to blacks who are (1) poor, (2) religious, (3) young, (4) middle-class, (5) working-class, (6) older, (7) elected officials, and (8) professionals. Possible responses were (1) not at all close, (2) not too close, (3) fairly close, and (4) very close. The raw measure of closeness to other blacks is the average response to the eight questions above, with a high value corresponding to greater closeness. If a respondent had a missing value for three or fewer categories, the mean response was used for those dimensions. Those with more than three missing responses were excluded from analyses. The alpha reliability coefficient for this scale is .81 (Broman, Neighbors & Jackson 1988).

Feelings of Closeness to Other Minorities

In addition to questions about closeness to blacks, respondents were asked how close they feel to (1) Spanish-speaking groups in the U.S., (2) American Indians, and (3) Asian Americans. Acceptable responses were (1) not at all close, (2) not too close, (3) fairly close, and (4) very close. The summary measure of closeness to other U.S. minority groups is the average answer to these three questions. Respondents with more than one missing value on the three questions were not included in further analyses.

Independent Variables

Childhood interracial contact is an attempt to quantify the level of contact an individual experiences with white people from birth to the beginning of adulthood. The NSBA asked respondents to estimate the racial composition of their (1) grammar school, (2) junior high, (3) high school, (4) college, and (5) neighborhood where they lived when growing up. Acceptable responses were (1) all black, (2) mostly black, (3) about half black, (4) mostly white, and (5) almost all white. The value of this variable is obtained by averaging the total score from the five questions across the number of categories with valid responses. Only those with missing data for all domains were dropped from analyses (Demo & Hughes 1990; Hughes & Demo 1989).

Parental socialization:[2] Respondents with children were asked if they have told their children anything about what it means to be black or how to get along with whites. If so, the content of those messages was obtained. Next, all respondents were asked if their parents had told them anything about what it means to be black or how to get along with whites when they were children. Those who said "no" were coded as having received no socialization. Respon-

dents who said "yes" and acknowledged socializing their children in the same way received a score corresponding to the message communicated to their children. All others were questioned about the content of messages received from their parents and those responses were coded.

The first step in converting these responses to a childhood socialization variable was to divide responses into three categories. The first group is labeled individualistic/universalistic. These respondents were given advice that denied the importance of race. The second is called integrative/assertive. These people's parents told them to maintain a positive group-oriented outlook. The third category is cautious/defensive. This group received messages about white prejudice and the importance of black power. The fourth group did not receive any socialization messages.

Next, three dummy variables were created. Each corresponds to one of the three types of socialization messages specified above and is coded 1 if the respondent received that type of message and 0 otherwise. The final step was to add the dummy variables that refer to the same type of message but to tally separately messages that made reference to blacks and those that made reference to whites. The result of this process is the creation of three measures of childhood socialization: individualistic/universalistic, integrative/assertive, and cautious/defensive. Values for each are (0) no messages of that type, (1) messages of that type about either what it means to be black or how to get along with whites, and (2) messages of that type about what it means to be black and how to get along with whites.

Intervening Variables

Outgroup orientation is represented by two measures and is based on the work of Jackson et al. (1991). The first is a global assessment of how whites view blacks. Interviewers asked, "On the whole, do you think most white people want to see blacks get a better break, or do they want to keep blacks down, or don't they care one way or the other?" Those who believed whites want to see blacks get a better break are coded 1. Respondents who answered either that "whites want to keep blacks down" or that "whites don't care either way" are coded 0.

The second measure of outgroup orientation considers respondents' personal networks. Interviewers asked, "Do you know any white person who you think of as a good friend — that is, someone to whom you can say what you really think?" Responses of "yes" are represented by a 1, and those of "no" are classified as 0.[3]

Traditional black church:[4] Respondents were asked whether they currently attend church and if so, how often. From the pool of people who reported attending church services at least once a month, individuals belonging to traditional black denominations (major national Baptist organizations, United Methodist, Christian Methodist Episcopal, African Methodist Episcopal, and African Methodist Episcopal Zion) are coded as 1 on this variable. Respondents who either attend church infrequently or are members of denominations other than those five are coded 0 (Ellison 1991).

Control Variables

Parents' socioeconomic status (SES): In the NSBA, respondents were asked the primary occupation of each parent when they were a child. A second question ascertained the parent's level of schooling. Due to the fact that so many respondents did not answer the education question, this information cannot be incorporated into a measure of SES. A further problem in determining socioeconomic status is that the NSBA provides neither a detailed occupational classification for respondents' parents nor enough information to construct one. The only information for assigning SES is a very broad grouping of parental jobs into one of seven categories: (0) no occupation; (1) farmer; (2) service worker or unskilled laborer; (3) operative, including transport; (4) craftsman, foreman, government protective service worker, or member of the armed forces; (5) clerical or sales worker; and (6) professional.[5] In the case that both parents were employed when the respondent was a child, only the occupation with the highest code is used (Demo & Hughes 1990; Hughes & Hertel 1990).

Complexion: This variable represents the direct transformation of a question interviewers were asked to answer. They recorded the respondent's skin color as (1) very dark brown, (2) dark brown, (3) medium brown, (4) light brown, or (5) very light brown.

Age: This is the respondent's reported age in years.

Female: This variable has a value of 0 for males and 1 for females.

South: Respondents were asked to name the state where they lived during most of their childhood. This information was converted into a dummy variable with 1 representing childhood residence in the South.

Results

The mean score on reported feelings of closeness to other blacks is 3.39 (maximum closeness = 4). This translates to a response between "fairly" and "very" close to blacks. In fact, only 1% of blacks reported feelings below 2 ("not too close"). The average respondent did not feel as close to other minorities as he or she did to other blacks. The mean closeness to other minorities is 2.11. The fact that the vast majority of respondents expressed greater solidarity with other blacks than with nonblack minorities suggests that what is examined in the course of this article is not the presence or absence of black identity, but variations in its degree.

In order to evaluate the total effects of childhood interracial contact and parental socialization on adult feelings of closeness to other blacks, ordinary least-squares regression coefficients for the reduced form equation are presented in model 1 of Table 1.[6] As predicted, the relationship between closeness to other blacks and interracial contact is negative and strongly significant. The coefficient for contact predicts that a change in childhood environment from "all black" to "almost all white" would result in the weakening of feelings of closeness by approximately one-sixth of one point. While this reduction is statistically significant, it may not be substantively important. We need to know the consequences for the individual and for the black community of changes in

feelings of closeness. This is a question that has not been adequately addressed in the literature to date, but it will be explored in the final section of this article.

To demonstrate the effect of controlling for closeness to other minorities on the apparent influence of childhood factors, model 2 is presented, which conforms to previous constructions of black identity (e.g., Broman, Neighbors & Jackson 1988; Demo & Hughes 1990) by not including person-of-color identity. Interracial contact has a greater negative effect on the isolated measure of black identity in model 1 than in model 2. All three measures of parental socialization have a stronger effect in model 2, thus substantiating the claim that messages about blacks and whites partially influence one's person-of-color identity.

Model 1 also indicates that parental socialization exerts an inconsistent influence on adult feelings of closeness to other blacks, a finding that contradicts past work (Demo & Hughes 1990; Jackson et al. 1991). While these studies conclude that all varieties of parental socialization influence closeness, the present analysis finds evidence of a positive effect of integrative/assertive and individualistic/universalistic parental messages, but no impact from cautious/defensive teachings about race. This discrepancy is the result of a difference in the construction of the closeness measure. The fact that messages exhorting a defensive posture toward whites are shown here to be inconsequential for black identity suggests their effect is on one's feelings of closeness to other people of color. Thus, when feelings of closeness to other minorities are controlled, as in model 1, the effect of this factor disappears.

Finally, it is of interest to note that model 1 has an R^2 of .2057. The fact that 21% of the variance in adult closeness to other blacks can be explained with childhood variables, closeness to other minorities, and demographic controls points to the importance of early experiences. However, it is also true that 79% of the variance in closeness is unaccounted for by the current model. While some of this unexplained variance is likely due to data noise and measurement error, it is improbable that these factors account for all the remaining variance. Therefore, it is reasonable to conclude that the effects observed for interracial contact and parental messages might be overwhelmed by other factors (e.g., adult characteristics or experiences) not included in this analysis.

Now that the magnitude and direction of the effects of childhood interracial contact and parental socialization on adult feelings of closeness to other blacks have been assessed, the analysis shifts to address the article's other stated goal — an evaluation of the process by which childhood factors exert their influence. The hypothesis is that interracial contact and parental socialization affect closeness indirectly, through outgroup orientation and participation in black churches, as well as directly.

The first step in evaluating this model is to examine the effect of childhood factors on black church involvement and outgroup orientation. Table 2 reports these results. As anticipated, increased interracial contact serves to lessen one's involvement with black churches. The move from an all-black to mostly black environment results in only a 9% decrease in the likelihood of attending a black church. However, the effect is not significant. The lack of a strong effect of interracial contact challenges the claim that involvement in a group's cultural activities is dependent on the extent to which that group exists in the individual's ecological range. As blacks move to more integrated environments,

theory predicts that black churches become less relevant for negotiating the matters of daily life and are replaced by class-based cultural manifestations (Gordon 1964; Stinchcombe 1975). No evidence is present in this analysis to suggest the abandonment of black institutions by integrated blacks.

Table 2 also indicates a positive effect of parental socialization on involvement with a traditionally black church. In fact, all three types of messages serve to increase the likelihood of church activity, though none of the estimates are statistically reliable at the .05 level. Lessons extolling the merits of blacks and encouraging interracial cooperation have the greatest effect, leading to a 20% increase in the likelihood of participation. The least important class of socialization messages, those that are cautious or defensive, has an effect about half as strong.[7]

The second and third columns of Table 2 present information about the effect of childhood factors on outgroup orientation. Beliefs about whether whites want to see blacks get better opportunities reflect a global assessment, while the presence of a white friend illustrates personal outgroup orientation. In support of the hypothesis that contact inspires comfort with one's outgroup (Gordon 1964; Park 1950), the coefficients for interracial contact are positive and significant for both global and personal assessments of whites. Despite the agreement in direction, there is a difference in the strength of these relationships. The change from complete segregation to a mostly black environment results in a 61% increase in the likelihood of reporting personal comfort, but only a 23% rise in the likelihood of expressing a positive global assessment of whites. The large increase in the likelihood of reporting a white friend is to be expected, since increased integration leads to a greater number of potential white friends. At school, the local playground, and neighborhood clubs, integrated black children interact and form primary relationships with many white boys and girls (Gordon 1964). The fact that such individuals continue to participate in relationships with whites into adulthood attests to the lasting impact of early positive interracial experiences.

Unlike interracial contact, the coefficients in Table 2 indicate mixed agreement between the predicted and observed effects of parental socialization on outgroup orientation. Individualistic messages increase the likelihood of a positive personal outgroup orientation by 28% but have little influence on global assessments. The latter finding is understandable in that this type of socialization is decidedly lacking in either positive or negative racial sentiments. While such messages do not affect ideology, they do matter for day-to-day decisions of who will be chosen as a friend. Individualistic renderings promote evaluations solely on the basis of character, thereby encouraging relationships with people of all races.

The second type of socialization message, one that is integrative in nature, has the strongest effect on both orientation measures. It increases both by approximately 40%. This finding is in agreement with previous work (Jackson, McCullough & Gurin 1988; Jackson et al. 1991), and indicates the long-term effectiveness of a philosophy promoting interaction between whites and blacks.

Finally, messages of a defensive and cautious nature increase the likelihood of a positive personal outgroup orientation by 33% but have an opposite though statistically insignificant effect on global comfort. This discrepancy suggests

parents who preach to their children about the omnipresent threat of racism have their greatest influence at the level of ideology. Instilling caution about whites on the level of personal interaction actually serves to foster a positive outgroup orientation. The reason for this association is not clear but may be a result of the mismatch between the degree of racism predicted by parents and that actually experienced by the child.

Table 3 presents the results of an OLS regression equation evaluating the full model suggested earlier in this article. Involvement with a traditionally black church is significantly related to black identity in the direction predicted by previous work (Ellison 1991). Blacks who regularly attend such institutions report feelings of closeness that are one-eighth of a level stronger than the sentiments expressed by fellow ethnics who are not active members of black churches. The fact that this relationship holds even with the constrained operationalization of identity employed in this analysis indicates that the black church is effective in encouraging a distinctly black identity.

Table 3 also provides information about the impact of outgroup orientation on adult feelings of closeness to other blacks. Contrary to expectations, there is no evidence that outgroup orientation negatively affects ingroup closeness. Neither dimension shows a statistically reliable estimate, and only the effect of global orientation is in the hypothesized direction. This finding conflicts with views expressed by Abrams and Hogg (1990) and Cooley (1902) that feelings of closeness are strongest when there are positive ingroup and negative outgroup sentiments. The absence of predicted effects of outgroup orientation suggests that these theories of group identity lack relevance to African Americans and indicates that the strength of black identity is independent of feelings about whites.

As predicted, the inclusion of black church participation and outgroup orientation in the model of adult feelings of closeness to other blacks reduces the observed effects of interracial contact and parental socialization. However, the magnitude of these changes is very small. The coefficient on childhood interracial contact is reduced by only 0.48%. The three measures of parental socialization fall by an average of 10%. That the indirect effects of these variables are so small testifies to the fact that outgroup orientation and participation in a traditional black church are not the mechanisms by which the examined childhood factors affect adult feelings of closeness to other blacks. Clearly, other processes are at work.

Discussion and Conclusions

This study has sought to answer two important questions about black identity. First, what are the effects of childhood racial environment and parental socialization on adult black identity? Past research has been clear in its conclusion that both of these factors are significant determinants of black identity. The study provides ample evidence for the claim that interracial contact weakens racial identity but finds mixed support for the argument that parental socialization strongly affects feelings of closeness to other blacks.

An explanation for this discrepancy was found in the definitions of black identity employed by different studies. Although defining identity in terms of feelings of closeness was seen to be quite common, the current study distinguished black identity per se from identification with other people of color. The importance of this distinction is that it allows factors affecting black identity to be distinguished from those relevant to one's nonwhite identity. Thus, the lack of consensus between this and other studies can be seen as an indication that warnings about omnipresent racial discrimination are important only for one's identity as a person of color. Previous findings that this class of parental messages is a determinant of feelings of closeness to other blacks are the result of poor specifications of black identity.

The conclusion that interracial contact, and to a lesser degree parental socialization, affect adult feelings of closeness to other blacks leads to an assessment of the second question motivating this research — what is the process by which childhood factors influence adult identity? Theory suggests that group identity is the result of positive ingroup sentiments and a negative outgroup orientation.

The present study provides insufficient evidence to support the conclusion that ingroup culture and outgroup orientation are the mechanisms by which childhood factors affect adult black identity. Consideration of indirect effects through these two mechanisms resulted in a minimal reduction in the strength of the direct effects of interracial contact and parental socialization. Furthermore, outgroup orientation showed no significant influence on closeness. These findings suggest that black identity may be independent of feelings about whites and strongly related to one's immersion in black culture. The question of how childhood interracial contact and parental socialization affect identity remains unanswered.

With an understanding of the effect of childhood factors on adult black identity and assessment of the hypothesized processes by which they operate, one final question remains — what are the consequences for the individual and the black community of an increase or decrease in feelings of closeness to other blacks? This is a very controversial issue. There is a sense in which a strong racial identity can be seen as an advantage for blacks. Black communities are plagued by a disproportionate share of this country's poverty, violent crime, and unemployment. In addition to the problems of black communities, individual blacks of all socioeconomic statuses continue to face discrimination. Wealth may be able to reduce the frequency of discrimination in personal interactions, but in public places all blacks are susceptible to random acts of racial prejudice (Feagin 1991). Those who advocate the strengthening of black identity hope that it will be accompanied by efforts to eliminate racial prejudice and other structural barriers that stand in the way of all black Americans. A common example used by advocates of black identity is the modern civil-rights movement. It saw teachers, ministers, and entrepreneurs join forces with domestic workers, students, and sharecroppers to overthrow the forces of legalized discrimination (Morris 1984).

Despite this example of how identity can inspire positive changes, some prefer to point to the dysfunctional nature of black identity (Steele 1990). From their perspective, black identity is the barrier that has hurt blacks' ability to take

advantage of the new opportunities created by affirmative action, racial quotas, and other attempts at righting past wrongs. A frequent example used by this side to illustrate their beliefs about identity involves school performance. They cite studies showing a trend among blacks to see academic excellence as a betrayal of the race (Fordham & Ogbu 1986). As a result, fewer blacks are in a position to capitalize on the efforts of universities to recruit a diverse student population, and those who are accepted often do not obtain a college degree. The net effect of a strong black identity is inadequate job skills and a discouraging future. If blacks ignored the pressures of the group and concentrated on achieving personal success, the result would be a slow, steady climb of the race from its current position near the bottom of the stratification system.

In order to resolve the debate between these two sides, much work needs to be done on the *consequences* of black identity. Some behaviors that might be examined are interracial dating and marriage, involvement in social protests, participation in programs aimed at helping blacks, residence in black neighborhoods, academic achievement, and financial success. By assessing the impact of black identity on these and other outcomes a better understanding of its desirability for the individual and society might be achieved. However, this new understanding will be misleading unless other types of identity are simultaneously considered. Blacks feel a sense of allegiance not only to their race, but also to their genders, classes, regions, generations, religions, and other groups with whom they share traits. Attention to the determinants of these identities and their associated behaviors is crucial to an understanding of how allegiances affect behavior. Only with this knowledge can social scientists provide a complete assessment of the costs and benefits of integration for black children and the black community at large.

Notes

1. In discussing the concept of identity it is necessary to draw a distinction between personal and group identity. Personal identity refers to the feelings one attaches to a component of the self. Personal efficacy and self-esteem are two dimensions of this type of identity. Where personal identity is expressed as an "I," the group identity is a "we." According to Cooley (1902), "One identifies himself with a group and speaks of the common will, opinion, service, or the like in terms of 'we' and 'us'" (209). Gordon (1964) employs a similar definition of group identity in referring to ethnics as possessing "a shared feeling of peoplehood" (24). While it is true that people often possess comparable group and personal identities based on a single characteristic, this correlation should not be misinterpreted as implying the strengths of the two identities need be equal (Cross 1985). In other words, an individual's assertion that he or she is proud to be black in no way assures that the same individual will feel a bond with other African Americans.

2. This variable is identical to the construction of parental socialization developed by Demo & Hughes (1990). Readers interested in a more complete discussion of its construction should refer to this previous article.

3. The correlation between the two dimensions of outgroup orientation is .24.

4. Participation in a black church is employed as a measure of black culture. While this is admittedly only a part of the activities and belief structure traditionally associated with blacks in the U.S., research has shown it to be a central element of the community (DuBois [1899] 1973; Morris 1984).

5. In the SES coding scheme, managers and officials are categorized as professionals. Proprietors of unincorporated businesses are excluded from the analysis. They represent less than 2% of the sample. Proprietors of incorporated businesses are categorized according to their business.

6. All analyses were conducted with the number of cases fixed at 1,452. This represents the number of cases valid across all five equations and thus provides for a consistent case base. Separate analyses with the number of cases unrestricted did not significantly alter any of the substantive results reported here.

7. The absence of evidence for strong effects of interracial contact and parental socialization on the likelihood of regularly attending a traditional black church are attributable to the inclusion of a regional control variable in the equation. Unreported analyses excluding region produced strong and reliable estimates for all but the cautious/defensive parental messages. With region added to the model, the coefficients on other variables decline dramatically. An example is childhood interracial contact. Before including regional controls, the coefficient on contact was -.3280. In Table 2 it is only -.0935. That translates to a difference of more than 20 percentage points in the calculated effect of contact on church participation. Further testament to the power of region in this equation is its observed coefficient. Table 2 indicates that childhood residence in the South increases the likelihood of adult involvement with a traditionally black church by 141%. In this and other equations throughout the article, region shows itself to be a tremendously important factor in many areas of African Americans' lives.

The Impact of Drug Use on Earnings: A Life-Span Perspective*

DENISE KANDEL, *Columbia University and New York State Psychiatric Institute*
KEVIN CHEN, *Columbia University*
ANDREW GILL, *California State University, Fullerton*

Abstract

Cross-sectional and longitudinal causal analyses were carried out on a longitudinal cohort of employed adult males (N~ 400) to investigate the relationship between various forms of drug use and earnings. By age 35, there are no cumulative effects of the use of illicit drugs on wages. Specification of the relationships at various stages of the life cycle reveals that the effects of illicit drug use are positive in the early stages of labor force participation (by the late twenties) but negative in later stages (by the mid-thirties). The negative impact of drug use on earnings appears to take more than a decade to manifest itself and is reflected in lower rates of earnings growth. We propose that a labor market theory of life-cycle compensation contracts and investments in training and the differential impact that different types of job changes have in the short and the long run among users and nonusers provide a partial accounting of the processes underlying the observed opposite relationships between drug use and earnings at different age periods. The importance of adopting a life-span perspective is highlighted by our findings.

Drug Use and Labor Force Achievement

Until recently, lifestyle factors, especially those indexing nonconforming values and behaviors, were rarely included in models of socioeconomic achievement. However, involvement in drugs, especially illicit drugs, may be an important factor to consider among the determinants of achievement.

Relatively little is known about the possible consequences of drug use on occupational careers and earnings in adulthood. Moreover, the effects of drug use on work roles and earnings documented to date are conflicting and somewhat puzzling. Illicit drug use has been shown to have negative effects on labor market activity, as reflected in increased job mobility (Kandel & Yamaguchi 1987; Newcomb 1988), number of missed work days (Robbins, Martin & Kaplan 1985; Zarkin, French & Rachal 1992), rate of unemployment, length of time unemployed (Kandel 1984; Kandel & Davies 1990; Miller, Cisin & Harrell 1978; O'Donnell et al. 1976; White, Aidala & Zablocki 1988), and reduced rates of promotion (Johnson & Herring 1989). Paradoxically, drug use has been found either to be unrelated to earnings (Jessor, Donovan & Costa 1991; Kaestner 1994; White, Aidala & Zablocki 1988) or to be related to higher wages. This positive relationship has been observed in several samples, including a cohort of New York State adolescents that we have followed into adulthood (Kandel, Mossel & Kaestner 1987), a cohort of former high school students in California (Newcomb 1988), and a large national cohort of young Americans, the National Longitudinal Survey of the Labor Force Experience of Youth, the National Longitudinal Survey of Youth (NLSY) (Gill & Michaels 1992; Kandel & Davies 1990; Kaestner 1991 1994; Mijares 1992; Register & Williams 1992). Some of the effects are modest in size.

Drug use could be expected to be associated with lower earnings through lower levels of educational attainment, less total work experience, poorer performance on the job, or lower commitment to traditional criteria of success. We noted above the consistent relationships observed between illicit drug use and job turnover. Illicit drug use is also a determinant of dropping out of high school (Mensch & Kandel 1988). And, despite the high prevalence of the use of illicit drugs in our society, young people who use drugs are usually less conforming and less attached to social institutions than nonusers (Kandel 1984; Johnston, Bachman & O'Malley 1984; Newcomb 1988). Illicit drug use has been shown to have negative consequences on the timing and quality of participation in adult social roles. Thus, drug use is related to a delay in the entry into marriage and in parenting, and to an increase in marital separation if drug use continues after marriage (Bachman, O'Malley & Johnston 1984; Newcomb & Bentler 1988; Yamaguchi & Kandel 1985a, 1985b). Drug users may have reduced aspirations and lower commitment to values underlying the striving for success. Drug use may also impair functioning on the job. The users' values and behaviors may send out unfavorable signals to employers, thereby hindering advancement on the job. Since drug use has been found to have negative consequences on dimensions of labor force participation that are positively related to wages, the observed null or positive relationships with wages are somewhat surprising and have puzzled researchers.

We here propose and document that a life-span perspective may help resolve the puzzle. The impact of drug use on earnings may vary depending upon whether the workers are in an early or a later stage of their careers. Indeed, Mullahy and Sindelar (1991, 1993), relying on diagnostic criteria specified by the American Psychiatric Association, found with respect to alcoholism no effect on income among 22 to 29 year olds but a negative effect among those 30 to 44 and 45 to 59. Kaestner (1994), using the 1984 and 1988

waves of the NLSY, estimated a fixed-effects model to control for unobserved heterogeneity in the sample, and found that the positive effect of illicit drug use on wages among NLSY men found in previous studies became negative, but statistically insignificant.

Analyses completed to date by ourselves and by others on the role of drug use on economic outcomes have been carried out only on young workers. Our own earlier analyses on a New York State cohort were carried out when respondents were 28 to 29 years old. Analyses on the NLSY are based on respondents at ages 18 to 31. We speculated at the time we reported our results that a potential negative impact of drug use on earnings may be lagged and may not manifest itself until later in a drug user's work career (Kandel, Mossel & Kaestner 1987). Similarly, Gill and Michaels (1992) proposed that drug users would eventually experience lower rates of wage growth than nonusers because rates of returns to working experience and education were lower for drug users in their mid-twenties.

This study delineates the effects of drug use on wage levels and wage growth by age groups and tracks the relationship between drug use and earnings among men from early adulthood to their mid-thirties.

Theoretical Background

DETERMINANTS OF EARNINGS

Earnings are primary indicators of socioeconomic achievement associated with a job. The human capital model constitutes the most basic model of wage determination. Among individual determinants of earnings, educational attainment and labor force experience are the most important positive factors (Blau & Duncan 1967; Featherman & Hauser 1978; Griliches & Mason 1973; Jencks et al. 1979; Mincer 1974; Willis 1986), with health status somewhat less important (Grossman 1972; Mullahy & Sindelar 1993). By contrast, the consequences of job mobility for earnings and earnings growth are unclear. Topel and Ward (1992) document that job changes are a major determinant of earnings of young people, accounting for at least a third of early-career growth and ultimately leading to the stable employment associated with mature careers. But job mobility may also reduce earnings (Topel 1991). The job search paradigm stresses that certain job shifts early in a career represent attempts by young workers to improve the match between their own needs and aspirations and the characteristics and rewards of a job. However, not all young workers will follow this pattern. Individuals are likely to differ for unobservable reasons in the types of voluntary changes they make. The negative consequences of job mobility can also arise if the prospect of changing jobs creates a disincentive for workers to invest in job-specific training (Borjas 1981).

Several years of labor force experience are required to identify the effect of education on earnings because job earnings immediately after completion of schooling do not adequately reflect the full returns of educational investment, even after controlling for the level of experience of workers who have completed school earlier (Griliches 1976, 1980; Mincer 1974). The best time to measure the effect of schooling on earnings is at the point of overtaking, after about eight

years in the labor force, when the returns to additional schooling are about equal to the opportunity costs of further investments in schooling (Mincer 1974). Not only education, but ability and background characteristics also appear to have varying impacts on earnings at different points in a career (Blau & Duncan 1967; Hauser & Daymont 1977). Wages in the first two years bear almost no relation to wages three to four years later (Meyer & Wise 1982).

A perspective that considers that the determinants of earnings may vary over the life of an individual would seem important.

VOLUNTARY AND INVOLUNTARY JOB MOBILITY

Of the relationships that have been observed between illicit drug use and characteristics of a work career, the relationships with job turnover and unemployment are the strongest and the most consistent (e.g., Kandel & Yamaguchi 1987). However, to the best of our knowledge, no investigation has examined such turnover as a function of whether it is voluntary, such as leaving for a better job, or involuntary, such as being fired. Although this distinction is somewhat difficult to sustain, for being fired may result from a worker's willful inappropriate behavior at work, a consideration of the nature of job turnover may be helpful in understanding the relationship between illicit drug use and earnings.

Voluntary and involuntary job changes may have different consequences for a person's earnings, whether short-term or long-term. Involuntary leaves have generally been found to be associated with lower earnings (Blank 1989). Voluntary job leaves can lead to unemployment. Some of these leaves, such as those due to a demotion or wage cuts, may have the same negative psychological impact as the experience of an involuntary job leave. Nevertheless, because the decision as to whether or not to leave lies with the individual, voluntary job leaves are distinct from involuntary leaves. The rates of involuntary job turnover will depend on characteristics of jobs and firms as well as of persons. We are particularly interested in individual characteristics that may increase the risk of such job turnover, and especially those related to the use of illicit drugs. Indeed, personal nonconformity that is reflected in the use of drugs may be an important determinant of involuntary job leaves, and as such may be a potential explanatory factor in the relationship between drug use and earnings.

LIFE-CYCLE PERSPECTIVE ON WAGE GROWTH

The controversial positive effect of drug use on earnings has puzzled researchers. We suggest that labor market theories of life-cycle compensation contracts and investments in training may help interpret the findings.

As noted by Lazear (1979), workers care about the present value of their own lifetime earnings, while firms are concerned about the present value of their workers' productivity. However, close supervision of workers is costly to firms, making it difficult to monitor and verify productivity (Carmichael 1989). One option for the firm is to sequence pay, whereby workers are paid a relatively low wage early in their tenure and a wage higher than they could get elsewhere based on their marginal productivity later in their careers to

compensate (Lazear 1979). By deferring payment a firm may induce a worker to perform at a higher level of effort. Workers are less likely to shirk because dismissal means surrendering the deferred compensation. This type of compensation scheme will appeal most to individuals with longterm goals who plan to work hard and long enough to get the deferred payment. Jobs that are long-term in nature are also more likely to be those that provide large firm-specific investments in training. The consequences of this process for wage growth over the life cycle have been emphasized by Mincer (1974) and by Borjas (1981). Borjas, for example, shows that job mobility leads to wage gains in the short run, but that nonmobile workers tend to achieve significantly higher wages over the long run (Borjas 1981). Job mobility is thought to affect the slope of the experience-earnings profile, with earnings growing at a slower rate on jobs that are not expected to be permanent. As Borjas notes, the prospect of labor turnover will create disincentives for investing in on-the-job training.

Two outcomes can be predicted based on this life-cycle perspective. First, young workers who opt for jobs that sequence pay or provide training will earn less early in their careers than comparable workers who do not make such investments. Second, earnings growth and, at some point, earnings will be higher for those who take these career paths than for others. These workers capture the deferred payment from wage sequencing and they share in the productivity gains resulting from the firm-specific investments.

Drug use may be differentially associated with the less favorable career path. As mentioned, drug users may have reduced aspirations and lower commitment to values underlying the striving for success. They have also been found to change jobs more frequently than nonusers (Kandel & Yamaguchi 1987). Thus, users in their twenties, at the beginning of their work career, may take jobs that are less likely to require a long-term commitment and provide much training. Nonusers, on the other hand, may accept a relatively low wage so as to qualify for jobs that offer long-term employment and in the future will pay higher wages than the market wage being earned by others. While the wage-sequencing and training hypotheses do not predict when the earnings of nonusers will overtake the earnings of users, they do suggest that nonusers will have higher rates of earnings growth.

We here report the results of analyses based on data obtained from a longitudinal cohort, when the members of the cohort were in their mid-thirties. We investigate the effects of different classes of drugs, cigarettes, alcohol, but especially the use of marijuana and other illicit drugs, on earnings. Our goals are to identify the potential impact of drug use on wages in different phases of workers' careers, as workers age from their late twenties to their mid-thirties, and to gain some understanding of the underlying mechanisms, in particular the potential role of labor market theory of wage compensation and of job turnover in accounting for the relationship between illicit drug use and wages. To parallel previous work in the field, we examine the impact of cumulative drug use at two specific ages. We then examine the impact of drug use on rates of earning growth at two different periods of the life span.

Data and Methods

We carried out cross-sectional and longitudinal analyses on members of a longitudinal cohort that we have followed for 19 years, from age 15-16 to age 34-35.

SAMPLE

The analyses are based on data for adult men derived from a follow-up cohort of men and women ($N = 1{,}160$), last interviewed at age 34-35. The cohort is representative of adolescents formerly enrolled in grades 10 and 11 in public secondary schools in New York State in 1971-72. The original two-stage sampling procedure involved the selection of a stratified sample of 18 high schools and a sample of students clustered by homerooms and stratified to represent the different grades within each school. Students who had not participated in the initial study and presumably were chronic absentees were also selected (and sampled at a lower rate) to permit unbiased estimates of the former student population at the time of the adult follow-up. Subsequent to the initial survey, three adult follow-ups were carried out in 1980, 1984, and 1990.[1] Overall, 71.7% of the initial adolescent target sample still alive was reinterviewed in 1990.

As we had found in prior surveys (Kandel, Raveis & Logan 1983), there were few statistically significant differences between participants and nonparticipants in the 1990 survey. However, compared with the initial high school sample, the reinterviewed sample reflected greater attrition of minorities than of whites: the sample includes 86.7% whites in 1990 compared with 79.6% initially.

Data were obtained through structured personal household interviews, which took on the average 90 minutes to administer. The schedule consisted almost exclusively of structured items with closed-end response alternatives and two charts designed to reconstruct the respondent's life and drug histories on a monthly basis. The drug histories were obtained from respondents who reported having used each drug ten times or more in their lives, so as to exclude experimental users. Information collected on the respondents' employment histories includes start and stop dates, part-time or full-time status, salary level, and reason for leaving the job for each job held.

Sampling weights took into account all relevant features of the sampling design. Adjustments for the differential participation of the target follow-up sample in 1980, 1984, and 1990 were also included in the weights.

ANALYTICAL STRATEGIES

Three major analyses and two variants were carried out on the basis of different statistical strategies, different subsamples, and slightly different definitions of the predictor variables. These strategies enabled us to move from considering a wide range of variables cross-sectionally to an increasingly smaller set of factors dynamically and to deal with three substantive issues.

(1) To predict levels of earnings, multiple regression analysis was conducted among all men working full time at two points in time: (a) in 1984, at age 28-29 ($N = 419$); and (b) in 1990, at age 34-35 ($N = 439$).

The specification of the single-equation model follows that of most human capital models (Mincer 1974; Mincer & Jovanavic 1981; Willis 1986). The dependent variable is the log of annual earnings; the explanatory variables include socioeconomic background variables, lifestyle and school performance measures ascertained in the initial high school survey (grades, degree of peer activity); total labor force experience, tenure on the current job, number of hours working, and individual characteristics at the time of the interview that could be related to both drug use and wages (e.g., education, marital status, health status and delinquency); and drug use. Tenure was entered together with total labor force experience in order to differentiate returns to employer-specific skills and training from those associated with general labor force experience (Altonji & Shakotko 1985; Mincer & Jovanovic 1981; Topel 1991). Labor force experience and tenure were also entered as quadratic terms reflecting the potentially diminishing returns to on-the-job training investments.[2]

The time-varying covariates were measured *cumulatively* up to each survey date, i.e., 1984 and 1990.

(2) To investigate the predictors of period-specific changes in earnings, two analyses were implemented: multiple regression and causal modeling.

(a) A variant of the multivariate regression model described above was estimated, where two classes of time-varying predictors, the drug-use variables and number of job changes, were measured *for the intervals* between the prior and the current interviews instead of *cumulatively*. The two intervals covered the four-year period from 1980 to 1984 and the six-year period between 1984 and 1990. Because earnings at the prior interview were also included as a predictor in the equations, this strategy enabled us to observe the specific effects of drug use and job turnover on earnings growth at different periods of a man's work career, from the mid- to the late twenties, and from the late twenties to the mid-thirties. This analysis allowed us to include a large set of covariates.

(b) A three-wave causal model was estimated on men who were working full time in 1980, at age 24-25, and who were still working (whether full time or part time) when reinterviewed in 1984 and 1990, at ages 28-29 and 34-35, respectively ($N = 401$). This multiwave longitudinal causal model permitted us to examine the potential reciprocal and dynamic relationships between drug use, job turnover, and earnings. The model, which includes a subset of the variables included in the multiple regressions, was estimated through structural equation modeling, LISREL 7 (Jöreskog & Sörbom 1989).

(3) To test a hypothesis suggested by the findings in step 2 above, variants of analysis 1b and analysis 2b were implemented. (a) An additional multiple regression was estimated on full-time workers at age 34-35, with all variables measured cumulatively up to age 34-35. The model was identical to that estimated in (1-b) above, except that the sample was restricted to those men who did not use any illicit drugs between ages 28-29 and 34-35 ($N = 347$) and earnings at age 28-29 were also included in the model. (b) As a final step, the three-wave causal model in analysis 2b was estimated separately for men who had not used any illicit drugs 10 times or more in their lives and those who

had. The multigroup comparison feature of LISREL (Jöreskog & Sörbom 1989) was used to estimate the equality of paths between the groups.

METHODOLOGICAL CONSIDERATIONS

Sample Selectivity

The different subsamples of men in the labor force vary in size in each of the three survey dates, 1980, 1984, or 1990. A number of respondents were not working at each survey. Sample selectivity may bias the estimates of wage levels if the likelihood of working is determined by unmeasured factors similar to those that determine earnings (Fligstein & Wolf 1978; Griliches, Hall & Hausman 1978; Heckman 1980; Mare, Winship & Kubitschek 1984). Inconsistent findings have been reported regarding the statistical significance of a sample selection correction term for employment in prior research linking drug use to wages. The term was found not to be significant by Kandel and Davies (1990) and Kaestner (1991), but to be significant by Gill and Michaels (1992) and Register and Williams (1992). In the linear models that we estimated, we included a correction term adjusting for the potential effects of differential propensity to work full-time, using the two-step procedure suggested by Heckman (1980). A probit model was run on the total sample of men to predict the likelihood of employment.[3] A correction term, the inverse Mill's ratio (λ) obtained from the probit model, was entered into the regression models. We calculated the correction terms with a set of parallel variables for both the 1984 and 1990 samples (see Appendix C).

In addition to its theoretical interest, the inclusion of job turnover in the models controls for other types of person-specific heterogeneity. The inclusion of labor force experience and tenure on the job raises additional methodological considerations related to unobserved heterogeneity. If there are unmeasured person and/or job-specific components of wages, tenure and/or experience, the latter variables and the error term in the wage equation would be correlated (Altonji & Shakotko 1985; Mincer & Jovanovic 1981). These correlations could bias estimates of all the coefficients, including the drug-use variables. The inclusion of measures of prior job mobility in the model controls for such person-specific heterogeneity (Mincer & Jovanovic 1981).

Specification of Drug Effects

A basic issue underlying any analysis of the impact of drug use on individuals is the extent to which the effects observed are due to the characteristics of individuals who self-select themselves into drug use or to the effects of using the drugs. The drug effects can be physiological as well as social and psychological. Being a drug user may lead one to remain embedded in a particular social context, which would sustain nonconforming lifestyles, including nonparticipation in expected adult roles. In the absence of experimental laboratory and field data, it is virtually impossible to separate out these two processes empirically. In the models we have estimated, in order to control for a possible selection effect in assessing the effects of drug use on the outcome being predicted, we controlled for factors that may be related to the onset of drug use, such as sociodemographic characteristics, behaviors measured in adolescence, education-

al attainment, other forms of deviance reflected in delinquent participation, and levels of adult social role participation, including current marital status and accumulated work experience both in the sample selection and the wage models.[4]

Other Statistical Considerations

In order to maximize the sample sizes, those who were absent from school at the time of the 1971 survey and for whom adolescent measures were not available were included in the analysis. A dummy missing variable was included in the models to account for missing data on the covariates measured in the 1971 survey.

A larger number of factors were entered in the multiple regressions than in the causal model. In order to reduce the complexity of the three-wave causal model, a subset of variables were selected, either because they were statistically significant in the regressions or because of their theoretical interest. As noted above, the time interval covered by the variables, whose value could change over time, differed in different models. In the first set of regressions, these variables, such as number of prior job changes or number of years a particular drug class had been used, were counted cumulatively from 1971 up to each interview. In the second set of regressions and in the causal model, these variables were counted cumulatively from the beginning to the end of each interval, i.e., between the 1980 and 1984 waves, and the 1984 and 1990 waves; in the causal model, a count was also made from 1971 to the first follow-up interview in 1980. The intervals covered 13 or 19 years in the first set of regressions, four and six years in the second set, and nine, four, and six years in the causal model.

DEFINITION OF VARIABLES

To be included in the analyses, a respondent had to be employed full-time at the time of the interviews included in each respective analysis, except for the causal model, where full-time work status was required only as of 1980, and part-time employment was acceptable for subsequent waves in 1984 and/or 1990. Of those employed full-time in 1980, 3.3% were employed part-time by 1984, and 2.6% by 1990. Employment at interview was defined as holding a civilian nonfarm job during the interview month, or one month before or after the interview if temporarily out of work at the time of the interview.

The dependent variable in all the regression analyses was a log measure of earnings, measured at the time of each survey. Current wages could be reported in the form of weekly, monthly, or annual earnings, with 14 equivalent precoded categories listed under each time period. The earnings were inputted at the midpoint of each category, and the annual equivalents ranging from $2,000 to $85,000 used in the regressions. The logarithm of earnings is the preferred functional form on theoretical and empirical grounds (Heckman & Polachek 1974; Mincer 1974), with the added advantage that the regression coefficients can be interpreted approximately as the percentage change in earnings due to a unit change in the covariate.

The following covariates were entered in the multiple regressions:

Background and Individual Characteristics (at the Time of Each Interview)

Race (black = 1, nonblack = 0)

Highest year of schooling completed by parents

Highest year of schooling completed

Current marital status (1 = married, 0 = others)

Self-assessed health status (1 = poor to 4 = excellent)

Delinquency index within the last 12 months, which counts the number of acts committed out of a list of 15 (scores range from 0 to 11) (α = .65)

Adolescent Characteristics (Measured in the 1971 High School Survey)

Peer activity index based on the extent of participation in any of five activities involving peers, i.e., getting together or hanging out with friends after school, dating, attending parties, or driving around [scores range from 10 (low) to 40 (high)] (α = .69).

Dummy missing on peer activity to account for those absent from school in the 1971 survey (27%) who are missing information on the adolescent variables

Self-reported grade point average (GPA). For school absentees, the value was imputed by regression from retrospective reports provided in the 1980 survey.

Characteristics of Labor Force Participation

For characteristics that can change over time, such as number of job changes, the time interval over which the variable was measured varied in different models.

Labor force experience (in years) was measured as of the first full-time nonfarm civilian job, up to 1984 or 1990 (depending on the model).

Labor force experience squared (years)

Job tenure: number of years in current job

Job tenure squared (years)

Average hours worked per week

Number and type of job changes. Each job termination was differentiated according to whether it was voluntary (e.g, getting a better job), involuntary (fired, layoff, temporary job), or other (family responsibility, illness). As we noted earlier, the conceptual distinctions among these categories are somewhat arbitrary. In the causal model, the last two classes were combined into a nonvoluntary category. The number of job changes consisted of the cumulative number of all full-time and part-time employment spells with different employers as of 1971 up to each interview date in the first set of regressions; the number during each of two different time intervals, between 1980 and 1984 and between 1984 and 1990, for the second set of regressions; the number during these two intervals and the additional period between 1971 and 1980 for the causal model.

Drug Use Variables

The drug use variables were defined so as to capture fairly regular and sustained levels of drug use. Because of differences in the use patterns of different classes of drugs and levels of involvement that these patterns represent, different criteria were used for the four classes of drugs under study. The cumulative number of years that drugs were used was obtained by dividing by 12 all months a particular class of drugs was used (at the specified intensity) since the 1971 survey. For the two specific periods in adulthood, the counts were restricted to the four-year interval between 1980 and 1984 and the six-year interval between 1984 and 1990.

Years of cigarettes smoking half pack a day or more

Years of using alcohol 4 or more times a week (near daily)

Years of using marijuana at least once a month

Years of using illicit drugs other than marijuana (cocaine, psychedelics, heroin and use without a prescription of minor tranquilizers, stimulants and sedatives) at least once a month. For the causal model, a latent factor for illicit drug use was estimated, with the manifest indicators being the two illicit drug use variables (number of years of use of marijuana and number of years of use of other illicit drugs). These cumulative drug use variables are highly correlated with an individual's severity of drug involvement. The longer the period of use, the greater the involvement. The correlations between total number of months a particular drug class has been used by each survey date and the frequency of use of that drug within the last year preceding the survey range from .66 to .86.

The detailed data on drug use and employment histories made it possible to define drug use patterns and number of job changes at different life stages: cumulatively by the late twenties and by the mid-thirties; and for specific periods of the life span. All time-varying covariates were evaluated as of the time of the current interview. As indicated below, different start dates were used in different models.

Sample Selection Correction Term

A term to correct for a potential bias in the earning equations due to selection into employment was calculated as per the procedure outlined above and entered into the regression models.

Means and standard deviations for the variables measured among full-time workers as of 1984 and 1990 are presented in Appendix A. On average, the men have completed two years of college and have worked eight years by 1984 and 13 years by 1990. They have held three jobs by their late twenties and five by their mid-thirties. Job leaves are evenly divided between voluntary and nonvoluntary types.

Results

As background to the analysis, it is useful to consider the extent of drug involvement by the men in the cohort. (See Table 1.) Most have experimented with alcohol, cigarettes and marijuana in their lives, and more than half have also tried illicit drugs other than marijuana. However, the proportions who are currently using illicit drugs decreases dramatically from the mid-twenties to the mid-thirties. While close to 80% of the men had used marijuana, by age 34-35, less than 20% reported using it within the last year. At that age, very few men were still using illicit drugs other than marijuana.

PREDICTORS OF WAGES AT TWO DIFFERENT TIME PERIODS IN THE LIFE-SPAN

As a first step, to replicate the analytical strategy used in prior research, we estimated multivariate regression models separately for full time workers who were 28-29 years old (in 1984) and 34-35 years old (in 1990). The results are presented in Appendix B. (The correlation matrixes are available from the authors on request.)

The cumulative impact of drug use on earnings depends upon the stage in a worker's life. By the late twenties, the cumulative impact of marijuana use over a 13-year period from adolescence to young adulthood is positive, while the effect of cigarette smoking is negative, controlling for significant human capital and background variables and correcting for sample selection bias. However, by the middle thirties, there is no apparent effect of cumulative illicit drug use over the 19-year interval since adolescence. The regression coefficients for use of marijuana and of other illicit drugs are zero. Illicit drug use from the late twenties to the mid-thirties may have a different relationship with earnings than use at a younger age.

Job mobility has a different impact on earnings, depending upon whether mobility is voluntary or nonvoluntary, and depending upon the man's age. Cumulatively, nonvoluntary changes lead to lower earnings by the late twenties, and voluntary changes lead to higher earnings by the mid-thirties. Voluntary changes have no impact on earnings at the younger ages and involuntary and other changes retain a slight negative impact at the later ages. The role of variables other than drug use on earnings is consonant with the human capital model. Controlling for all other covariates, educational attainment is consistently the most important predictor of earnings. The other predictors are model-specific. Total labor force experience, extent of peer activity as an adolescent, and good health have a positive impact up to the late twenties only. Longer working hours are associated with higher wages by the mid-thirties only. Delinquent participation has no effect at either time period.

The negative coefficient for the sample selection correction terms is statistically significant and implies that whether or not a man was employed full time is not a random process. If employed, individuals not included in the model might have lower earnings than those included (Dolton & Makepeace 1987).

TABLE 1: Drug Use at Different Periods among Men Who Worked Full Time in 1980 and Were Still Working in 1984 and 1990

	Ever Used by 1990 Age 34-35 (Percent)	Used Past Year in 1980 Age 24-25 (Percent)	Used Past Year in 1984 Age 28-29 (Percent)	Used Past Year in 1990 Age 34-35 (Percent)
Alcohol	99.2	94.4	92.9	91.2
Cigarettes	79.9	51.2	49.2	43.7
Marijuana	79.0	53.0	38.8	17.9
Any other illicit drug[a]	55.5	20.0	18.8	8.3

(N = 429)

[a] Any illicit drugs other than marijuana, including cocaine, psychedelics, heroin, nonmedical use of minor tranquilizers, sedatives, and stimulants.

PERIOD-SPECIFIC PREDICTORS OF CHANGES IN EARNINGS

The absence of cumulative effects of drug use by the mid-thirties compared with the positive effect observed by the late twenties suggests that the eventual rate of earnings growth might become lower for drug users than for nonusers.

Two-Wave Multiple Regressions

As a first step, in order to identify the effects of drug use within a specific period of the life span, we estimated multivariate regression models at two different age periods: (1) from the mid- to the late twenties, and (2) from the late twenties to the mid-thirties. The number of job changes and the years of drug use were measured for each specific time interval. The other covariates were identical to those entered in the first regressions described above. These models estimate the impact of drug use on *changes* in earnings, i.e., wage growth, from 1980 to 1984 and from 1984 to 1990, since wage levels at the beginning of each interval were controlled. (See Table 2.)

Differences in the impact of drug use on earnings are clarified when the analyses are restricted to specific age periods and time intervals (Table 2). From the mid- to the late twenties, controlling for earlier wage levels, the use of illicit drugs other than marijuana has a slight *positive* effect on wage growth. However, between the late twenties to the mid-thirties the use of illicit drugs other than marijuana has a statistically significant *negative* effect on wage growth. This negative effect rate in the six years preceding the interview at age 34-35 is stronger than the positive effect in the four year period preceding the interview at age 28-29.

Not surprisingly, prior earnings is the strongest predictor of subsequent wage growth. The impact of involuntary changes is negative but only during

TABLE 2: Parameter Estimates from Multiple Regressions Predicting Log Annual Salary at Ages 28-29 (1984) and 34-35 (1990) among Male Workers with a Full-Time Civilian Nonfarm Job[a]

the younger age period. In contrast to the cumulative models, voluntary changes have no significant impact on wage growth within each period and other types of job changes have a negative impact. Being married becomes significant (positive) from the mid- to the late twenties.

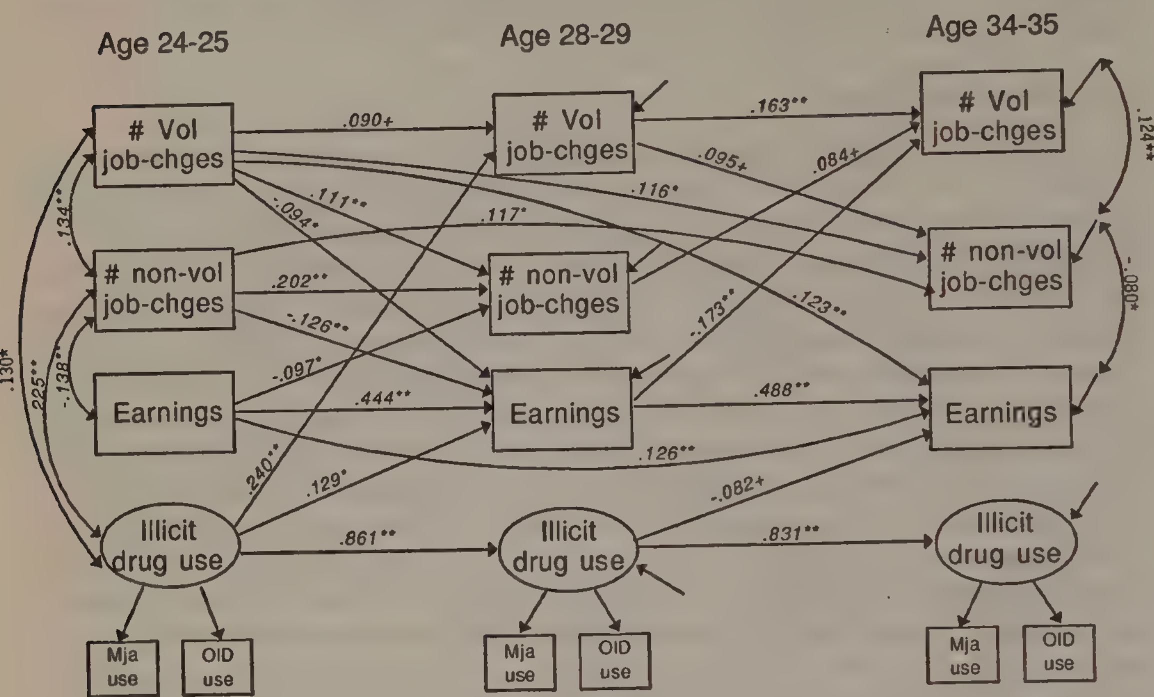
Three-Wave Causal Model

The three-wave structural equation model estimated among men, who had a full-time job at age 24-25 and were still working at ages 28-29 and 34-35 (Figure 1), provides a more powerful test of the relative impact of drug use on labor force performance over time than the multiple regressions. It also makes it possible to analyze the reciprocal and dynamic effects of drug use, earnings and job turnover on each other. Because of estimation constraints, a smaller number of variables were included in the causal model than in the regressions. The same variables were included in all three waves, except for race. Involuntary and other job changes were combined into a single variable, nonvoluntary job changes. To control for measurement error, we introduced a latent construct for the use of illicit drugs and allowed the error terms to correlate over time. Coefficients for job mobility, earnings, and illicit drug use are displayed in Figure 1. Race, years of schooling, self-reported health status and marital status were also controlled, but their coefficients are not shown. Since delinquency had no significant effect in the multiple regressions and its exclusion would not lead to a misspecification of the drug effects, it was not included in the causal model. Standardized coefficients are displayed in the figure.

The positive impact of illicit drug use on subsequent wage growth in the twenties and its negative impact in the thirties is confirmed. A reestimation of the model constraining the paths from drug use to income during each interval to be equal to each other indicates that the paths are significantly different from each other ($p<.01$). (The chi-square is 145.46 for the unconstrained model, 154.17 for the constrained model). By contrast, there are no significant direct or indirect effects from earnings to drug use. Controlling for initial levels of job turnover, illicit drug use predicts increased voluntary job mobility in the early stage of the work career, but does not predict either voluntary or nonvoluntary mobility in the later stage. The three-wave model clarifies the results regarding the impact of voluntary job changes by age 34-35 obtained in the cumulative and period-specific multiple regressions. Job mobility, but especially nonvoluntary job changes, early in a career (by age 24-25) have negative effects on subsequent wages earned in the late twenties; job mobility in the late twenties, whether voluntary or nonvoluntary, has no direct effect on wages six years later. However, voluntary job changes have a time-lagged positive effect on wages over the ten year period from the mid-twenties to the mid-thirties. Level of earnings in the mid-twenties (1980) reduces subsequent nonvoluntary job turnover while earnings in the late twenties reduces subsequent voluntary turnover.

Earnings and nonvoluntary job changes each have a time-lagged effect on themselves over the ten-year period, over and beyond the intermediate direct effects that they have from one period to another during that interval. We cannot, however, eliminate the possibility that other variables may have affected the same measure at different times. There is another time-lagged effect: earlier

FIGURE 1: Three-Wave Causal Model of Drug Use, Job Changes and Earnings[a]



$\chi^2 = 145.5$, df = 121, p = .064, AGFI = .93

[a] Male full-time workers at age 24-25, working at age 28-29 and 34-35. Standardized coefficients are shown. Race, year of schooling, self-reported health, and marital status are controlled for, but not shown. Nonsignificant paths, correlated measurement errors of drug use over the three surveys, and error correlations at age 28-29 are also not shown. Error correlation of earnings and nonvoluntary job changes is -.160**; correlation of nonvoluntary and voluntary job changes is .115*.
(N = 401).

+ $p < .10$ * $p < .05$ ** $p < .01$

voluntary job changes predict nonvoluntary changes. In fact, one type of job turnover also predicts subsequent participation in the other: voluntary job turnover in the mid-twenties is related to an increase in subsequent nonvoluntary turnover four years later, which in turn increases the risk of voluntary turnover in the following six years.

DIFFERENTIAL EFFECTS OF DRUG USE ON WAGE GROWTH: AN INTERPRETATION

The negative effect of illicit drug use on wage growth in the thirties is consistent with the notion that drug use lowers productivity; the positive effect in the twenties is controversial. As we noted in the introduction, labor market theories of life-cycle compensation contracts and investments in training may help

interpret and reconcile these period-specific findings. The hypothesis is that drug users early in their careers take jobs with less career potential and eventually their rate of earnings will decline compared to that of nondrug users. In a preliminary test of the first part of the hypothesis, we examined the types of jobs held by drug users and nonusers at age 24-25 in terms of their advancement potential. We attached to each job a code reflecting the training requirement of that job, as indexed by the specific vocational preparation defined by the Department of Labor (U.S. Dept. of Labor 1991:1009). This code reflects "specific vocational preparation" (SVP), the amount of time required to learn the techniques needed for average performance in a specific job-worker situation, and reflects vocational education, apprentice training, in-plant training, on-the-job training, and essential experience in other jobs (U.S. Dept. of Labor 1991:1009). There is a statistically significant difference between the SVP scores of drug users and nonusers, with the users scoring lower than the nonusers. This supports our hypothesis.

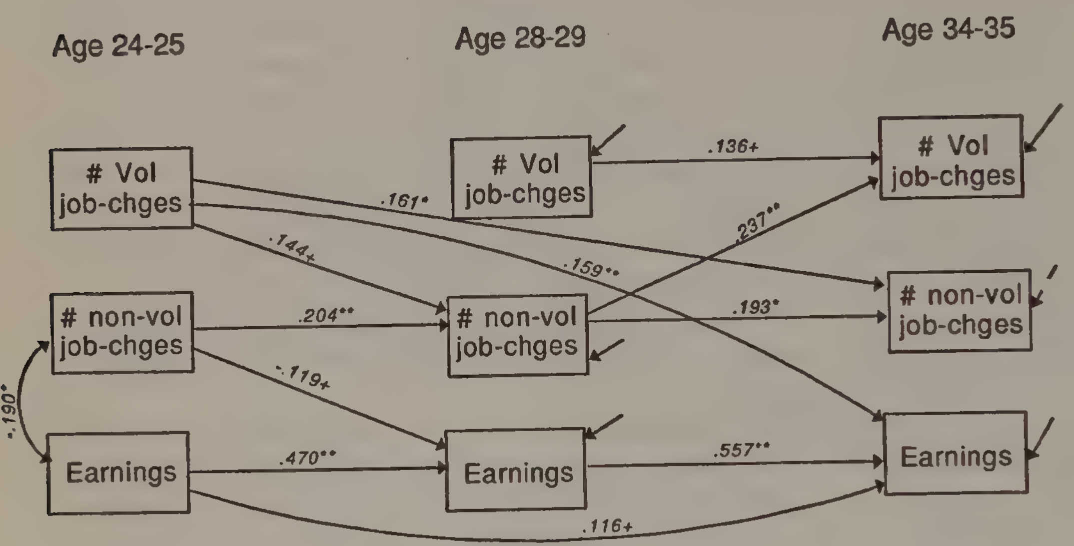
The second part of the hypothesis led to a reformulation of the multiple regressions and a specification of the three-wave model presented above in Figure 1. In a first step, we compared drug users who had stopped using drugs by their late twenties with persons who had never used any illicit drugs. We restricted the age 34-35 sample to those individuals who did not use drugs between ages 28-29 and 34-35 in order to isolate the time-lagged effects of earlier drug use on earnings growth from the negative period-specific effects of use documented above. The change in earnings over the six-year interval was regressed on the same predictors as those included in the multiple regression (see Appendix B, model 2), with the exception that cumulative drug use was measured up to age 28-29 (1984). The other individual and work related characteristics were measured up to age 34-35 (1990). Cumulative monthly use of illicit drugs other than marijuana by age 28-29 has a negative effect ($\beta = -.015$, $p < .05$) on earnings growth between the ages of 28-29 and 34-35 (full model not presented). Thus, while drug use has a positive relationship with earnings in the twenties, it yields a lower rate of wage growth that persists even after cessation of use.

Although at first paradoxical, this interpretation of a labor market effect is not inconsistent with the time-lagged positive effect of voluntary job changes on earnings observed over time (see Figure 1). In parallel to the labor market theory of wages, the job search paradigm proposes that certain job shifts early in a career represent attempts by young workers to improve the match between their own needs and aspirations and the characteristics and rewards of a job. We hypothesize that those most likely to follow this pattern are young workers who do not use drugs.

In a second step, re-estimation of the three-wave causal model separately for men who never used drugs (Figure 2) and those who did (Figure 3) support the hypothesis and provides further insights into the mechanisms that underlie the observed relationships between drug use and earnings. The two models are identical, allowing a test of the equality of paths among drug users and nonusers through the multisample analysis feature of LISREL.

The models provide several noteworthy findings.

FIGURE 2: Three-Wave Causal Model of Job Changes and Earnings: Nondrug Users[a]



$\chi^2 = 55.23$, df = 51, p = .318, AGFI = .878

[a] Male full-time workers at age 24-25, working at age 28-29 and 34-35. Standardized coefficients are shown. Race, year of schooling, self-reported health, and marital status are controlled for, but not shown. Nonsignificant paths are also not shown. (N = 161).

+ $p < .10$ * $p < .05$ ** $p < .01$

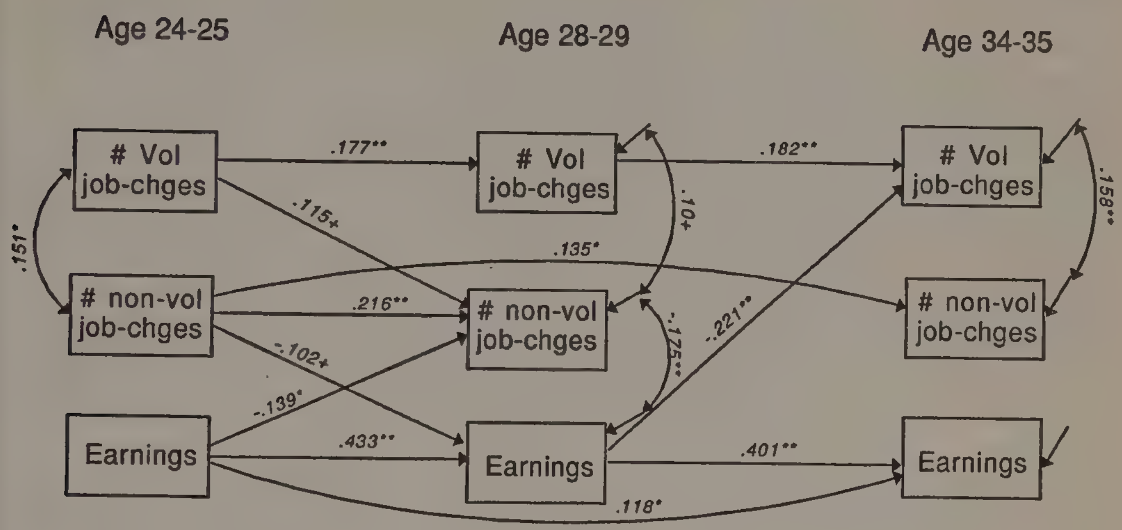
(1) For everyone, mobility early in one's career, i.e. by age 24-25, is crucial to long-term wage gains by age 34-35, either directly or indirectly. Mobility between ages 24-25 and 28-29 has no direct impact on wages at age 34-35.

(2) For all individuals, earnings in the mid-thirties are directly determined by earnings in the late twenties rather than directly by job mobility in the preceding six years.

(3) Nonvoluntary job changes are related to lower wages from the mid- to the late twenties for all individuals (see Figures 2 and 3). Drug users, however, experience more such types of job turnover than nonusers early in their career: $\bar{X} = 1.20$ for users, .68 for nonusers, difference significant at $p < .01$. There is a correlation of .225 ($p < .01$) between illicit drug use and nonvoluntary job leaves at age 24-25 (see Figure 1).

(4) Voluntary job mobility by the mid-twenties has a time-lagged positive effect on the wage growth of nonusers by the mid-thirties ($\beta = .161$, $p < .05$ for nonusers, −.060, nonsignificant, for users). However, a test of the equality of these two paths indicates that they are not statistically significantly different

FIGURE 3: Three-Wave Causal Model of Job Changes and Earnings: Ever Drug Users[a]



χ^2 = 39.57, df = 49, p = .830, AGFI = .938

[a] Male full-time workers at age 24-25, working at age 28-29 and 34-35. Standardized coefficients are shown. Race, year of schooling, self-reported health, and marital status are controlled for, but not shown. Nonsignificant paths are also not shown. (N = 240).

+ p < .10 * p < .05 ** p < .01

from each other. The relatively small size of the sample may be in part responsible for this result. It may still be the case that drug users do not reap the positive benefits of voluntary job leaves experienced by nonusers.

(5) The effect of earnings in the late twenties on earnings in the mid-thirties is smaller for users ($\beta = .401$, $p < .01$) than for nonusers ($\beta = .557$, $p < .01$). The difference between the two paths is statistically significant at $p = .01$. The higher wages of drug users early in their careers do not lead to higher wage growth subsequently.

Thus, drug users suffer three types of handicaps relative to nonusers: (a) They appear not to experience the time-lagged positive effects of voluntary job leaves on wage growth. (b) They experience stronger cumulative negative effects on wage growth from nonvoluntary job changes early in their career, from the mid to the late twenties, since they experience many more such leaves than nonusers. And, as noted above, earnings in the late twenties, and not job mobility, determine earnings in the mid-thirties. Finally, (c) drug users

Conclusion

Given the adverse impact of drug use, especially illicit drug use, on an individual's physical and psychological well being and the assumption that occupational achievement is associated with ability and productivity, drug use would be expected to lead to lower levels of productivity and consequently to lower labor force achievement and lower earnings. Most existing research reports the opposite with respect to earnings: the effect of illicit drug use is positive (Gill & Michaels 1992; Kaestner 1991, 1994; Kandel, Mossel & Kaestner 1987; Register & Williams 1992), or nonsignificant (Kandel & Davies 1990; Kaestner 1994). However, prior research on the impact of illicit drug use has been consistently based on samples of young adults, the majority of whom are in their twenties. The opportunity to observe individuals beyond their twenties over a longer period of labor force participation provides new insights regarding the impact of drug use on labor force performance, specifically earnings and rates of wage growth.

This study reveals that the impact of drug use on earnings depends upon the stage in the life-span. The controversial positive effect of illicit drug use on men's earnings disappears by the mid-thirties. Illicit drug use between the ages of 28-29 and 34-35 is related to lower earnings growth by age 34-35. Translated in terms of percentage changes, an additional year of using other illicit drugs between the ages of 24 to 29 leads to a 4% increase in rate of earnings growth but use between the ages of 29 to 35 leads to a 7% decrease in growth rate for each additional year of use. Mullahy and Sindelar's (1993) analysis of the impact of alcoholism on income found positive effects through the late twenties and negative effects at older ages. Furthermore, the authors also concluded that alcoholism was more highly related to labor force participation than to wages, a conclusion similar to the one we have reached with respect to illicit drug use. Economists stress that the full returns of higher educational attainment for earnings may not be achieved for many years after entry into the labor force. The point of overtaking may be as long as eight years (Griliches 1976, 1980; Mincer 1974). Similarly, the negative impact of drug use on earnings appears to take more than a decade to manifest itself and is observed among those who stopped using drugs as well as among those individuals who continue to use illicit drugs at a time in the life cycle when most of their peers have terminated their use.

Our prior results (Kandel & Yamaguchi 1987) led us to expect that the underlying process between lowered earnings and illicit drug use might be accounted for by increased job turnover. The relationships between drug use, job turnover and earnings are complex. The results of the causal analysis suggest that the effect of job turnover is indirect and is due to two different processes, both originating in the mid-twenties. At that time, drug users are more likely than nonusers to experience nonvoluntary rather than voluntary job changes. Nonvoluntary job turnover is related to lower subsequent growth in wages. In addition, drug users do not appear to experience the time-lagged positive effects of voluntary job mobility experienced early in their career on their wages later in their career. (Note also, that, controlling for prior job

mobility, the effect of drug use on job mobility appears only early in a work career, up to age 28-29. However, job mobility at that age does not directly predict reduced subsequent earnings by age 34-35.)

Thus, the causal model that we estimated also provides some important insights regarding processes related to labor force participation and psychosocial development in adulthood other than those specifically related to drug involvement. By differentiating type of job separation, we have documented that not all job mobility leads to lower income (Blank 1989; Sicherman & Galor 1990). Voluntary job changes eventually improve workers' wages among those who do not use drugs while nonvoluntary changes negatively affect wages for all workers. As mentioned, Topel and Ward (1992) associate early job changes with the movement toward mature careers. Our findings showing the different effects of early voluntary job mobility on earnings growth for drug users and nonusers suggests that individuals may differ for unobservable reasons in the types of voluntary changes they make, and, consequently, that drug use aids in identifying this individual heterogeneity.

One interpretation of the processes underlying the opposite relationships between drug use and earnings at different life stages is based on labor market theories of life-cycle compensation contracts and investment in training. We speculate that, early in their careers, drug users may choose higher paying jobs over higher subsequent growth potential, while nonusers make the opposite trade. These latter workers may accept low wages so as to obtain jobs that are ports of entry to job ladders that pay higher earnings in the future and because they have an incentive to share in the costs of firm-specific training. Our analyses have provided only a preliminary test of these hypotheses, which remain to be tested further.

Other interpretations can also be advanced. It may not be until the testing phase, possibly during a longer period of attachment to a particular work site, that the employee's wages would reflect levels of productivity. As suggested by French (1993), wages may not be a good indicator of an individual's loss of work productivity. An employer may not be able to adjust an individual's wages to the individual's specific level of productivity. Rather, increased marginal costs resulting from a drug user's lower productivity will be reflected in lower wages for all workers or higher prices paid by consumers. Or, the potential negative impact of drug use on productivity due to its negative physical effects may reflect lengthy cumulative use and may take many years to become manifest. Alternatively, the apparent effect of drug use may mask the effect of other unmeasured variables, such as personality or motivational variables. It is these variables, and their changes over time, which would account for the divergent relationships observed between income and drug use in the twenties and in the thirties.

A life-span perspective, however, specifies that the positive association between illicit drug use and earnings is typical of earlier as opposed to later stages in individuals' work careers, when the association turns negative. When the human capital-earnings relationship is viewed as a process whereby younger workers engage in training investments, job search, and long-term employment contracts to enhance future earnings potential, a predictable pattern of life-cycle earnings by drug-use status emerges. Training investments and

long-term employment contracts require that workers sacrifice present earnings for higher wage growth. If drug users are less willing to make these early sacrifices, they could conceivably earn higher wages at younger ages, other things equal. We propose that a labor market theory of life-cycle compensation contracts and investment in training and the differential impact that different types of job changes have in the short and the long run among users and nonusers provide a partial accounting of the processes underlying the observed relationships between drug use and earnings.

Notes

1. With a completion rate of 81% of those living, 1,325 persons were interviewed in 1980, at the mean age of 24.7. Four years later in 1984, 1,222 persons, comprising 92.5% of the 1980 samples (excluding 4 deceased), were reinterviewed at age 28-29. Of these, 1,160 were reinterviewed in 1990 at age 34-35, with a completion rate of 95.7% (excluding 10 deceased persons).

2. We considered and rejected the possibility of estimating the reciprocal effects of drug use and earnings by instrumental variable techniques, since the causal model we tested, as described in 2b indicated no effect from earnings to drug use.

3. The variables included in the probit models to calculate the correction term for sample selection bias into employment for the 1984 and 1988 regressions are listed in Appendix C together with the coefficients. Two adolescent variables measured in 1971 were included in the probit models but not the regressions. The minor delinquency index is a seven-item self-reported measure that assesses delinquent activities during the three months preceding the 1971 survey, including being sent out of class by a teacher or taking things of little or some value. Self-esteem is a six-item short form of the Rosenberg's self-esteem scale (Rosenberg 1965). The LIMDEP program was used to calculate the inverse Mill's ratio (λ) from probit models.

4. An alternative method to control for selection effects is to estimate an endogenous switching regression model (Maddala 1983), which would require separating the sample into users and nonusers and appending selectivity terms constructed from first-stage probit estimates of the drug-use choice to each earnings regression (Gill & Michaels 1992; Kaestner 1991). These probit estimates would be based, in large part, on those same variables believed to be related to the onset on drug use. Three factors caused us to reject this formulation. First, separating the sample into use categories would result in very small sample sizes for the earnings regressions. Second, our interest is in measuring the effect of a continuous measure of cumulative drug use on earnings. The standard switching regression formulation requires a discrete endogenous threshold variable. Finally, these models are very sensitive to deviations from normality. Thus, including those factors leading to drug use directly into the earnings regression is the preferred strategy for controlling for selection effects in the present case.

Pathways to Voluntarism: Family Socialization and Status Transmission Models*

THOMAS JANOSKI, *Duke University*
JOHN WILSON, *Duke University*

Abstract

Participation in voluntary associations is usually explained by a Weberian theory that uses human capital variables; however, Durkheimian theory suggests the importance of parental socialization and family status variables. Using a three-wave panel study, this article models the changes in social participation that people experience while moving from high school to parenthood. Voluntary participation is accounted for in part by the transmission of socioeconomic status, but family socialization through example and value modeling are often more important. When self-oriented (occupation and profession) and community-oriented (service, church, community, fraternal, and neighborhood) types of participation are distinguished, the status transmission theory explains self-oriented but not community-oriented participation. Family socialization explains community-oriented but not self-oriented participation. Thus, theories of voluntarism must be differentiated according to the type of voluntary association concerned.

People join voluntary associations to achieve a variety of personal objectives which they could not obtain by acting alone. Participation in voluntary associations can cover such disparate activities as "team bowling, card-playing, voting as a member of a committee, belonging to a neighborhood improvement association, protesting racial discrimination, interacting with kin and friends, [and] contributing to the Community Chest" (Edwards & Booth 1973:1). In some of these cases the organization resembles a "mutual benefit association" because the prime beneficiary of the collective action is the membership itself. In other cases, the organization resembles a "service organization," because a client group (e.g., the homeless), not the membership, is the prime beneficiary (Blau & Scott 1962:140). The question thus arises whether the same sociological theory can be used to explain participation in both types of organization. In this article,

** We wish to thank Lynn Nonnemaker for research assistance. We benefited from critical readings by Charles Clotfelter, Anne Tickamyer, and the anonymous reviewers.* *Direct correspondence to Thomas Janoski, Sociology Department, Box 90088, 268 Sociology/Psychology Building, Duke University, Durham, NC 27708. we propose a conceptualization of voluntary association behavior in which these activities are divided into self-oriented associations (e.g., professional and union groups) and community-oriented associations (e.g., community volunteers, church-related organizations). We argue that different explanations are needed to resolve why people engage in each type of voluntary association, and that the factors that explain participation in one type have little to do with participation in the other.

Theory

Two sets of theories have guided the study of voluntary association memberships. The first is associated with Emile Durkheim. One of the theories within this set Hechter (1987:20) calls the "normativist perspective," because it sees joining as an expression of the solidarity that comes from adherence to a set of corporate obligations. The obligations, or norms, are learned in the same way that other norms are learned, informally through family and friends, and formally through schools, churches, and the workplace. It is also possible that such norms are acquired from the mass media (Payne et al. 1972:228). Of all agents of socialization, the most influential is the family (Gecas 1981:170). If this is true, and if the normativist perspective has anything to contribute to the understanding of voluntarism, the disposition to join should be transmitted directly from one generation to another. Mechanisms of family socialization include modeling, reinforcement, role playing, labeling, and social comparisons (Bandura 1977).

As Hechter (1987) points out, the normativist perspective does not exhaust the possibilities of Durkheimian theory. From the writings of Durkheim, and a contemporary, Georg Simmel, has emerged the "structuralist perspective." From this perspective, whether or not people will join and become active in secondary associations depends very much on the network of social relations in which they are embedded.[1] Voluntary action is contingent on the degree of social integration of the individual into society. As noted by Moen et al. (1989), social integration is a concept historically applied to collectivities, but it can also describe the multiple roles of individuals, where it "denotes the concrete involvement of individuals with various aspects of a collectivity" (635). This aspect of Durkheimian theory would lead us to expect that employed people would be more active than the unemployed, that married people are more active than single, that parents are more active than the childless, and so on. In other words, people become more or less active depending on the number of social ties they have.

This aspect of Durkheimian theory has a number of obvious applications: it suggests that participation in the labor force promotes voluntarism; that people with roots in the community will be more active; that joining produces more joining. It also suggests that families influence voluntarism in ways other than those suggested by the normativist perspective. From that perspective, voluntarism is the expression of internalized norms inculcated by parents. Children resemble their parents because of what they have been taught by them. From the structuralist perspective, voluntarism is the expression of structural isomor-

phism: children resemble their parents because their roles and statuses become identical; i.e., they have themselves become parents (besides, in most cases, remaining children).

Only a few studies of voluntary associations have included family variables in the analysis (for notable exceptions see Klobus-Edwards et al. 1984; Knoke & Thompson 1977). This neglect is surprising because a number of studies have shown that both family of origin and family of procreation are important influences on two very common types of voluntarism — political party membership and church participation (Jennings & Niemi 1981; Sandomirsky & Wilson 1990). These studies suggest that socially active parents produce socially active children. This would provide support for the social learning theory that people "get most of their ideas by observing the actions of others who serve as models" (Heiss 1981:102). The family of procreation effect is explained by structural theory: when people become like their parents in having children they become active in social groups like their parents.

The second set of theories of voluntary association memberships is associated with Max Weber. A Weberian theory of voluntary association memberships attributes more significance to socioeconomic factors: voluntary action is driven, or made possible, by socioeconomic interests and resources, and will change as these interests and resources change. Thus, when McPherson (1981:718) finds that people in higher status occupations are typically more active in voluntary associations, he attributes this to their being more attractive to, and more likely to be recruited by, a voluntary organization, and to their being more likely to reap "social contact" rewards from voluntarism. It is indeed true that, for many people in high-status occupations, voluntary association membership is almost part of the job. In many cases membership dues are paid by the employer. Not surprisingly, active membership in voluntary associations is almost always found to be positively correlated with income, educational and occupational status levels (Axelrod 1973:40; Babchuk & Booth 1973:26; Pearce 1993:65). While these separate dimensions of socioeconomic status tend to be quite highly correlated, there appears to be some agreement that education is the best predictor of social participation among this group of variables (McPherson & Lockwood 1980).

Socioeconomic status, of course, can be traced in part to family background, but the principal determinant of voluntarism according to Weberian theory is *current* socioeconomic resources and interests, since life chances are affected by market position. The theory does not, therefore, rule out the influence of the family, but assumes that it will be indirect, through the station in life parents provide their children. Describing the pattern of intergenerational transmission of values, Dalton (1982) contrasts the "attitudinal" pathway (141), which would depend for its efficacy on direct personal contact, presumably before the child leaves the home, and the "social milieu" pathway, which consists of the kind of social relationships a given parental socioeconomic background makes possible. Acock (1984) supports the view that parent-child similarities are as likely to be the product of the intergenerational transfer of status as of individual psychosocial influence. Glass, Bengtson and Dunham (1986) also suggest that generational similarities and differences can be due to either socialization or transmission of status.

This article's purpose is to show that one does not have to choose between these sets of theories to explain social participation. Voluntary action can take a wide variety of forms, and it is possible that one sociological theory explains one form better than another. It is a standard feature of sociological writings on voluntary associations to categorize them into different types. The distinction between "instrumental" and "expressive" is perhaps the most familiar (Edwards & Booth 1973), but the parallel distinction between "purposive" and "solidary" associations is also often drawn (Clark & Wilson 1961). Instrumental or purposive groups are those aimed mainly at some tangible outcome for the participating individuals or a client group, while expressive or solidary groups are those organizations where participation itself is the primary source of satisfaction (e.g., fellowship). If there are indeed different types of voluntary associations, then perhaps there are different reasons for belonging to them and different social factors associated with membership.

Most scholars of voluntary associations agree on the difficulty of categorizing them (Pearce 1993:18). Not only are many organizations multipurpose but, on the individual level, membership can mean different things to different members. Even those who have adopted the instrumental/expressive distinction are obliged to admit mixed "instrumental-expressive" types into their analyses (e.g., Edwards & Booth 1973:1-2). The instrumental-expressive dichotomy itself has been criticized for being gender biased, since most of the organizations typically categorized as instrumental are heavily male consigning females to the expressive category. Just as important, the instrumental/expressive categorization leaves little room for organizations whose primary purpose is building community. Organizations are assumed to be either intended to further the interests of their members or purely inward-looking and expressive.

Community building is an important aspect of voluntarism, and a conceptual scheme that obscures this function is deficient. Our method of categorizing voluntary associations is to think of them in terms of self- versus community-orientation. Some forms of social participation have as their chief goal furthering an individual's self-interest, while others are intended more to protect the interests of a community as a whole. Our self-oriented type is close to the instrumental type, but our community-oriented type is intended to cluster together those associations whose ostensible mission is the improvement of a community. This distinction is similar to that proposed by Pearce (1993) who, drawing on Thompson (1976), distinguishes between voluntary associations and voluntary organizations. Voluntary associations are groups of people who share an interest and have agreed to pursue it jointly. "Association members are both 'owners' and 'consumers' of the association's output and need please no one but themselves" (Pearce 1993:18). This corresponds to our self-oriented type. Voluntary organizations, on the other hand are engaged in generalized exchanges with nonmembers. "They produce a service or product for outsiders" (Pearce 1993:18). This corresponds to our community-oriented type.

Most social surveys of voluntary association memberships use a fairly standard coding scheme now associated with the General Social Survey. It prompts respondents to indicate membership in any of the following kinds of groups: church-connected, lodges or fraternal, neighborhood clubs, sports teams, informal clubs like sewing circles, business or professional groups, service

groups, ethnic or racial groups, and labor unions. We define business/professional, trade union and veterans groups as self-oriented. We define church, fraternal, neighborhood, and service organizations as community-oriented. We thus try to distinguish voluntary activity which is primarily oriented to increasing or protecting benefits, furthering business or occupational interests and the like, from those activities that are oriented primarily to caring, community welfare, and social improvement. The division is, of course, simplistic. It ignores the fact that many organizations are multipurpose, or provide side benefits in addition to their main benefits. It also ignores differences within each category: business groups vary in their degree of emphasis on service to the community, just as churches and fraternal orders vary in the degree to which they cater mainly to the needs of their own members.

Some organizations exist for companionship and entertainment. These groups, such as sports and hobby organizations, neither promote income and occupational interests nor benefit the larger community in any direct way. Consequently, we eliminated sports teams, informal clubs, and ethnic and racial associations from both the self- and community-oriented categories. Much volunteer work, of course, centers around youth-oriented programs like Little League Baseball. Participation in these kinds of activities is, however, often difficult to classify. Sports activities that one engages in for amusement hardly qualify as voluntarism. Making the distinction is even more difficult in the case of ethnic and racial associations. These groups often provide dinners, dances, and other entertainment, but they also involve both community action for the improvement of members' life changes and opportunities for community building with other groups. Because these groups had a strong entertainment element and involved significant mixing of self and community elements, we eliminated them from the analysis rather than force them into one or the other category.[2]

It is our contention that Weberian theory accounts for participation in self-oriented organizations, while Durkheimian theory accounts for participation in community-oriented organizations. Participation in self-oriented organizations is based largely on a calculus of costs and benefits, or structured largely by selection procedures that favor certain socioeconomic groups over others because the exchange of membership for service is beneficial to the organization. Conversely, participation in community-oriented groups is only marginally dependent on resources and is more of an expression of the individual's socialization and degree of social integration. If our argument is sound, it also follows that Durkheimian theory cannot account for participation in self-oriented organizations, and Weberian theory cannot account for participation in community-oriented organizations.

Data Source

The two theories could be tested using cross-sectional data, since one indicates that voluntary association memberships are associated with current degree of social integration while the other sees voluntarism as associated with current social status. However, they are best tested by panel data, for they actually

describe different paths to voluntarism. In the one path, parents bestow status on their off-spring, which in turn leads to voluntarism, and they have this effect regardless of their own degree of participation or their children's degree of social integration. In the other path, parents teach lessons in voluntarism and provide role models for their children, and they have this effect regardless of the human capital they bestow on their children.

This study uses data from the Youth-Parent Socialization Panel Study (YPSP), collected by the Survey Research Center at the University of Michigan (Jennings & Niemi 1981). The first wave of the study in 1965 yielded 1,699 randomly selected high school seniors from a national probability sample of high schools, representing a 99% response rate. A randomly selected parent of each student was also interviewed, resulting in 1,562 completed interviews for a 93% response rate. The second wave was collected in 1973, and retained 1,348 (80.8%) of the youths from the original panel, and 1,179 of the parents (75.5%). In 1982, 1,135 of the students were re-interviewed and 898 of the parents. For the purposes of this study, we concentrated on that group of students who were interviewed in all three waves and who had a parent interviewed in both 1965 and 1973 ($n = 924$).

Dependent Variables

Our dependent variables describe levels of participation in voluntary associations. Participants in the Youth-Parent Socialization Panel study were shown a list of organizations "to which people may belong" and asked to indicate which they were members of, if any. Those who indicated they belonged to an organization were asked separately to specify their level of activity in the organization, ranging from "not very active," through "fairly active," to "very active." Types of organization on the list were: church-connected, fraternal, neighborhood, sports, informal, professional or business, service, ethnic, and labor unions. In supplementary questions, respondents were given two chances to mention organizations they belonged to that were not on the provided list and were asked to indicate their level of activism in them.

We recoded these basic variables to make them more manageable and to facilitate a better test of our theory. First, we "folded in" the answers to the supplementary questions, recoding the answers to allocate them to existing categories. We added veterans' groups to the trade union category; political clubs and youth-related groups to the neighborhood category; charitable enterprises to the service group category; and country clubs and hobby groups to the informal club category (not included in the final analysis). The numbers involved in this re-coding were small. Second, we combined the answers to the first two questions to create a variable measuring membership and level of activism simultaneously. The recoding reads: 0 = not a member; 1 = member, but inactive; 2 = member, fairly active; 3 = member, very active. Third, we created a participation index for each respondent in each year. We did this by summing the scores 0-3 for each of the organizations listed.

Our fourth step was to select two groups of organizations to be our measure of self and community-oriented participation. In the first category we

placed business/professional, trade union, and veterans groups. In the second category we placed church-related, fraternal, neighborhood (and youth related and political), and service organizations. The result of these efforts is two groups of dependent variables: self-oriented measures of participation in 1973 and 1982; community-oriented measures of participation in 1973 and 1982. These categories measure very different types of social participation. There is no correlation between membership in self-oriented and community-oriented organizations among our respondents in 1973. The correlation between self-oriented and community-oriented memberships in 1982 is significant ($p = .0013$) but somewhat small ($r = .10$).

Independent Variables for the Socialization Theory

To predict community-oriented voluntarism in 1982, our study will use parent's voluntarism in the early waves of the panel study as a measure of role-modeling. The socialization theory predicts that parental example will have an immediate impact on the child. We therefore examine the student's own social participation while in high school. In addition, since it is reasonable to suppose the voluntary association memberships are somewhat "sticky," we also use the student's social participation in adolescence to predict later voluntarism. The data set does not contain a direct measure of voluntary association memberships for the student while in high school. As a surrogate, we created a measure of student's high school social participation from a number of questions put to the high school seniors concerning the level of their participation (if any) in a number of extracurricular activities (Hanks 1981). These included being a member of a school athletic team, school band, school debating team, publication board, hobby club, school subject club, occupation club, and neighborhood club. Students were also asked if they had ever run for political office, and we included this in our measure of social participation. Responses were coded to match adult social participation, from 0 for not a member to 3 for a very active member. The student social participation index for 1965 was created by summing the scores on these variables. We made no attempt to discriminate at this stage between self- and community-oriented participation.

The same measures of voluntary association memberships are used for the parent as specified in the section on the dependent variable, with one exception. In the first wave of the survey, there are three cases: both parents were interviewed, only the mother was interviewed, or only the father was interviewed. Using one parent's data as a basis for the independent variables would have resulted in a large number of missing cases (mothers are missing cases where the father is interviewed, fathers are missing cases where the mother is interviewed). We therefore decided to create a single "parent variable." This consists of the mother's score where the mother was interviewed and the father's score where the father was interviewed. In order to remain consistent with our parents' socioeconomic measure, where the father's score is used in the case of both parents being interviewed, we decided to take the father's voluntarism score where scores from both spouses are available. Since mothers

might be said to have a slightly stronger tendency to volunteer than fathers, this is a conservative measure of parental influence on volunteering.

Thus, there are six participation variables for parents: (1) the overall participation index for 1965 and 1973, (2) the community-oriented index for 1965 and 1973, and (3) the self-oriented index for 1965 and 1973. In the analysis that follows, we use only variables in item 2.

The assumption of family responsibilities is an important part of the Durkheimian model. We measured both marital and parental status. A marital status question was asked of students in 1973 and again in 1982. We collapsed the responses into married (coded 1) and single (coded 0). The parental status variable came from different questions in 1973 and 1982. Respondents were asked in 1973 to list the members of their household and their relationship to them. A measure of number of children was computed from this variable. In 1982, respondents were asked if they had any children and, if so, how many were sons and how many were daughters. These responses were combined to yield a count of number of children. Marital status and parental status are, of course, quite highly correlated. Multicollinearity problems makes using both variables in a regression model troublesome. Since our theory places most weight on the role of children in fostering voluntary association memberships, we use the parental variable in the regression analyses.[3]

Independent Variables for the Status Transmission Theory

Human capital is typically measured in terms of income, education, and occupational status. The Youth-Parent Socialization Study data set provides information on all three for both parents and children. The income variable was the simple amount of income coded into increments of $2,000 until "$35,000 and above." For education, students in 1973 and 1982, and parents in 1965 and 1973, were asked their current level of education. The item used in this study codes responses according to the number of years completed. Noncollege postsecondary education received an additional one year added to high school education. The occupational coding scheme varied from year to year: we converted all measures of occupation into the Duncan SES code for 1970. The code runs from 1 to 99. As previous researchers have discovered, the three measures of socioeconomic status tend to be highly correlated with each other and with the dependent variable. In the multivariate analysis, therefore, we dropped occupational status from the model.

Although coded in the same way as the students, parent's income and occupation presented special problems given our need to construct a single-parent variable by combining the father's and mother's responses into a single variable. Education of the mother may be comparable to the father, but many of the women were housewives in both 1965 and 1973 and their reported income and occupational status could not be considered an accurate record of a family's socioeconomic circumstances. To deal with this problem, we took the mother's report of head of household's income in 1965 and the mother's report of spouse's income in 1973 in order to construct a head-of-household variable. The result is a variable that largely reflects father's income and occupation;

however, mother's income and occupation are used in single-parent households or when the mother is the head of household.

Men are more likely to belong to voluntary associations than women (Edwards & Booth 1973:23). Since we are interested in the effects of status transmission, and given the likelihood that men and women would be differently affected by these status transmission processes, we include gender as a control in the status transmission model. For consistency, we introduced gender into the socialization model, but it was unrelated to participation in 1965, volunteering in 1973, or volunteering in 1982. Since it made no difference to the other associations in this model, we dropped it from the socialization analysis. Gender was coded 1 for male and 2 for female.

Methods

Our analysis is guided by two hypotheses:

Hypothesis 1. Community-oriented participation but not self-oriented participation is explained by socialization variables.

Hypothesis 2. Self-oriented participation but not community-oriented participation is explained by status-transmission variables.

To test these hypotheses, we constructed two models, both aimed at predicting variation in the dependent variable, the degree of participation in voluntary associations in 1973 and 1982. The Weberian model assumes that social status will have an impact on current social participation and that current social status is to some extent dependent on parent's social status. The Durkheimian model assumes that social participation is partly inherited directly from parents' own participation and is also a function of current family statuses. The main part of the analysis consists of using Durkheimian theory to estimate variations in community-oriented participation and Weberian theory to estimate variations in self-oriented participation. We then look at how well each theory explains variation in the "wrong" kind of voluntarism (e.g., socialization model explaining self-oriented voluntarism).

Results

Table 1 reports rates of activism for students in three waves and parents in two. Allowing respondents multiple mentions meant that ranges on these variables varied from 0-13 to 0-25. The means were therefore standardized to make comparisons possible. The 1965 "voluntarism" variable for students is not directly comparable to the others in the table since it measures participation in extracurricular activities while in high school and not voluntary associations. Nevertheless, it is a decent proxy measure of the individual's disposition to social participation.

In a recent cross-national comparison of voluntary association memberships, using data gathered at the same time as the third wave of the Youth-Parent Socialization Panel Study, Curtis et al. (1992) found that 72.7% of Americans belong to some kind of voluntary association. This was easily the highest

[a] NA Indicates that the student's high school participation could not be divided into community-oriented and self-oriented variables in 1965.

percentage among the nations compared, and much higher than the mean reported in Table 1 for the nationally representative sample used in this study. This discrepancy can be accounted for in a number of ways. First, the wording of the question used in the study drawn upon by Curtis et al. (1992) is ambiguous as far as religious organizations are concerned, for the interviewer prompt includes "churches and religious organizations." Many respondents are clearly including church membership in this list, which is inflating the rate. We do not include church memberships (e.g., Catholic Church) in our list, but membership in church-related organizations (e.g., Knights of Columbus, Legion of Mary). Second, the data reported in Table 1 measure not only membership but activism. Curtis et al. also recognize that membership is not the same as

participation and report "working membership" rates: the percentage for active members falls to 31.8% for all associations and 18.9% for all secular organizations, participation rates much closer to but still lower than those reported from the Youth-Parent Socialization Study.

Where most respondents are reporting no active voluntary association memberships at all, it is to be expected that the overall means will be low. The column for total voluntary association participation shows high school students have the highest rate. This is largely an artifact of the different question used. High school extracurricular activities are far more structured and integrated into the school social system than are voluntary associations in the wider community. In addition, some high school extracurricular activities are, if not mandatory, subject to peer group pressure to belong.

Voluntary association memberships in early adulthood have a mean about half that of high school social participation. This is partly an artifact of the stricter measure of voluntarism used in 1973, but it is also in line with a pattern of voluntary association memberships over the life course, in which memberships are low among young adults (Curtis et al. 1992:147; Knoke & Thompson 1977).

Student participation increases from age 26 to 35. Parents' participation also increases from age 45 to 55. The parents' rate at age 45 is slightly lower than the student's rate at age 35. This means an artificial "rolling cohort effect" is not produced by the table. On the whole, however, previous findings that voluntary association participation increases with age are replicated. The break in the upward curve between students who are 35 in 1982 and parents who are 45 in 1965 has more to do with the differential cohort effects of parents growing up from 1938 to 1946, when voluntary associations had been significantly reduced by the depression and state mobilization, and their sons and daughters growing up from 1965 to 1973, when voluntary associations greatly increased due to increased social mobility and antiwar activity.

In comparing columns 2 and 3, a life cycle and an age effect are seen with the two different types of organizations. At age 26, students are more involved in self-oriented associations, but by the time they reach 35 students are slightly more involved in community-oriented participation. The parents are much more involved in community-oriented participation at the age of 45, and this gap grows even larger by the time they reach the age of 55. Thus, over time, community-oriented participation increases, while self-oriented activity declines after a high point at the age of 35. We interpret this as young adults needing to make a successful transition into the labor force. In this process, many join and participate in self-oriented voluntary associations to promote their career. However, by the age of 35 their careers tend to be more or less established. These adults now have families and their voluntary association activities shift to family concerns which involve a more community-oriented kind of participation. Both age and life cycle effects are important and complementary.

The zero-order correlation coefficients between the independent variables and the three measures of voluntary association memberships are shown in Table 2. The first columns show the correlations for overall participation; the second column shows the correlations for community-oriented participation; and the third column shows the correlations for self-oriented participation. The

top panel displays the coefficients for the socialization model; the bottom panel shows the coefficients for the status transmission model. For overall student voluntary association participation in 1982, few socialization variables are significant, while the effects of many of the socioeconomic status variables are both strong and significant. As might be expected, students' own socioeconomic status is more strongly associated with voluntary association memberships than is their parent's socioeconomic status.

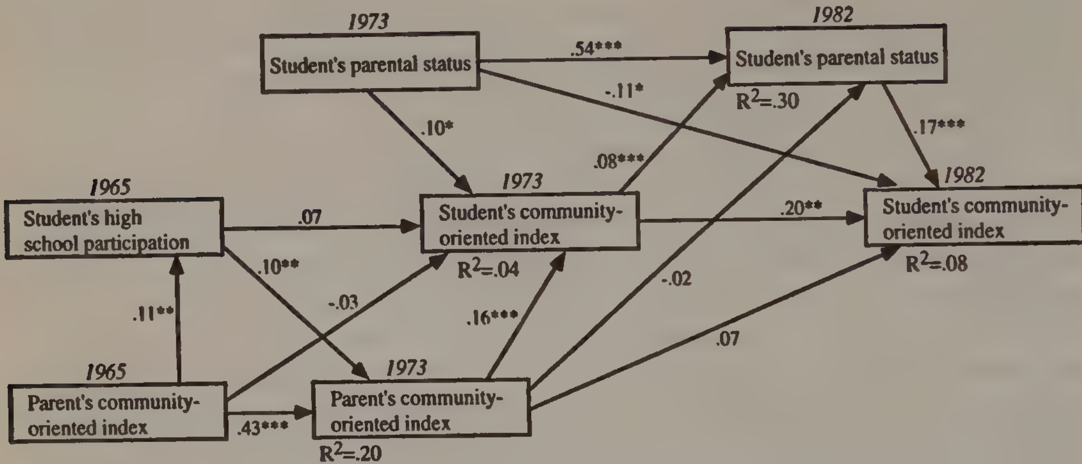
The main point of Table 2 is to contrast columns 2 and 3. In the case of column 2, we hypothesized that most of the variables in the top panel would be significant while few of the variables in the bottom panel would be so. This is indeed true. All but number of children in 1973 and parent's voluntary association memberships are significant in the top panel; only education in 1982 is significant in the lower panel. In the case of column 3, we anticipated that no variables would be correlated in the top panel and all would be correlated in the bottom panel. The top panel actually displays more significant variables than we had anticipated. However, the significant variables are negatively, not positively, related to membership in self-oriented associations. Married people with children are less likely to belong to this type of organization. The bottom panel fulfills our expectations. Only parent's income in 1965 and parent's occupational status in 1973, factors quite far removed from the dependent variable, are unrelated. Female gender is negatively related to membership in self-oriented associations.

The zero-order coefficients provide preliminary but nevertheless substantial support for our two major hypotheses. However, they say little about how the several variables are related to each other and to the dependent variable. In other words, they say little about the different "paths" to voluntary action earlier described. For this, path analysis is necessary.

Figure 1 presents the socialization model used to estimate variations in community-oriented participation in 1982. Students whose parents were active in community-oriented associations in 1965 are more likely to be active themselves while in high school. However, high rates of social participation in high school have no carry-over effect on voluntarism once the student leaves school. There is an indirect path of influence of parents on children, however, and that is through parent's community-oriented activism in 1973 which is, in turn, dependent on their prior activism in 1965. Parents who are active in 1973 are more likely to have children who are also active. This association holds, regardless of the student's prior social participation, and regardless of their parental status, which is itself positively related to community-oriented activism.

The fact that parental influence is sustained across the two waves is especially noteworthy. It is to be expected that parents will have more impact on their children when those children are in their mid-twenties than when those children are in their teens. The gap between the parents in 1965, with an average age of 45 and the youths, with an average age of 18, is larger in subjective terms than the gap in 1973, when the parents are 55 and the students are 26. It is undoubtedly true, also, that the social participation of parents and children becomes more similar over this life-course transition because, structur-

FIGURE 1: Socialization Path Model Explaining Community-Oriented Voluntary Association Participation



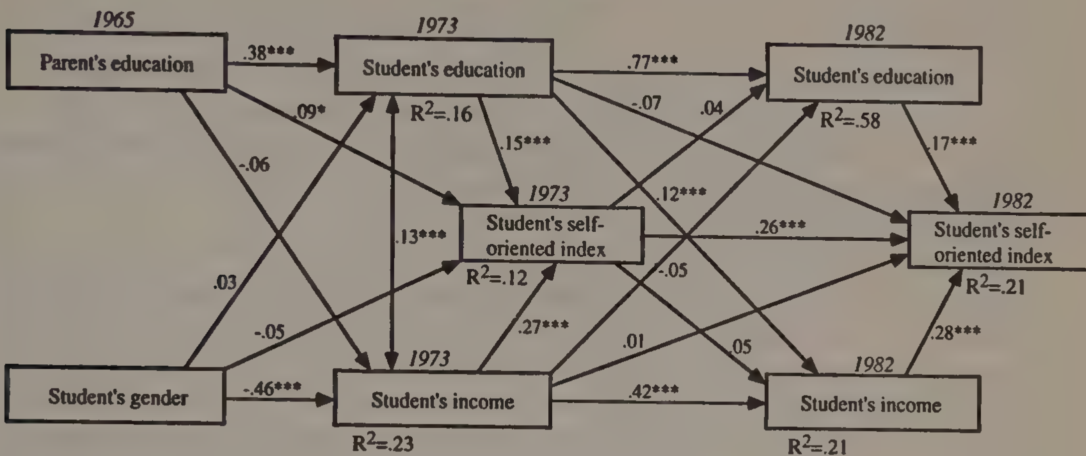
* $p < .05$ ** $p < .01$ *** $p < .001$

ally, the parents and children are becoming more similar; but this effect of parents on children is net of parental status for the children.

Community-oriented activism among students who have reached their mid-thirties, as expected, is influenced by their prior voluntary association memberships. However, the relationship is not particularly strong. This might be explained by the data reported in Table 1 showing that many respondents became active between the ages of 26 and 35. The impact of parent's participation has by this time faded. As predicted, parental status has a positive effect on voluntary association memberships in 1982, slightly stronger than the effect in 1973. The negative effect of parental status in 1973 on community volunteering in 1982 is interpretable in light of the parental status in the 1982 variable. Those who had become parents by 1973 had begun having children as early as nineteen. Their children could have been anywhere between age 1 and 7 in 1973. By 1982 these children would have been between 10 and 16. Those who became parents sometime between 1973 and 1982, however, would have had much younger children in 1982. We believe that the age of the children helps explain the negative sign. People who had not added to the number of children by 1982 had, by that time, children who were too old to pull their parents into social participation. The path to community-oriented voluntarism is thus clear from this diagram, where the effects of parental modeling and social integration are visible, despite the fact that not much of the total variance in community-oriented voluntary association memberships is explained.

Figure 2 reports the results of the test of the self-oriented model. This model accounts for much more of the variance (20%) than the socialization model does for community-oriented participation. Family status background, as measured by the level of education of the parent, has a small but significant impact on the likelihood of volunteering in 1973, even when a number of other factors are

FIGURE 2: Status Transmission Path Model Explaining Self-Oriented Voluntary Association Participation



* p < .05 ** p < .01 *** p < .001

controlled. Family background also has an indirect effect, as predicted by the theory, through the respondent's own educational achievement by 1973. Highly educated parents produce highly educated children who, in turn, are more likely to be active in voluntary associations of the self-oriented type. Both education and income have positive effects on voluntary association memberships in 1973. Indeed, the effect of income is stronger than that of education. Gender has no direct effect on the chances of voluntarism. However, women earned less money than men in 1973 and this in turn makes it less likely that they will be active.

Like community-oriented participation, self-oriented participation reproduces itself. People who were active in the second wave are more likely to be active in the third wave than those who were inactive. However, both education and income have powerful and highly significant effects on 1982 membership in this type of voluntary association. Again, level of income is more important than level of education, suggesting that membership, and particularly activism, is based partly on the ability to pay (e.g., professional dues) or make donations.[4]

Figures 1 and 2 provide substantial support for the theory that voluntary association memberships are acquired through two different pathways, depending on the type of membership involved. Community-oriented activism is almost directly inherited: the activity and example of the parents has a powerful influence on that of the offspring. When those offspring begin to resemble their parents in roles and responsibilities, they begin to act like them. Membership in self-oriented voluntary associations, on the other hand, is inherited from parents indirectly. Parents make it possible for children to acquire the human capital that makes membership in such organizations desirable and feasible, although they are more likely to do this for their sons than their daughters.

The argument that socialization variables explain community-oriented voluntarism and human capital variables explain self-oriented voluntarism would be more convincing if it could be shown that socialization and role modeling have no impact on self-oriented participation and that the inheritance of human capital has no impact on community-oriented participation. In other words, if it could be shown that the "wrong" theories do not work. Table 2 has already strongly suggested that this is the case. Zero-order correlations between status variables and community-oriented participation are weak at best; those between socialization variables and self-oriented participation are either insignificant or negative.

The most appropriate test of the "wrong" theory would be to repeat the path analyses reported in Figures 1 and 2, switching the independent variables. Since (as we anticipated from the correlation table) this resulted in a path diagram with a mass of insignificant paths, we have conducted a simpler contrast, reported in Tables 3 and 4, where we show only direct effects on voluntarism in 1973 and 1982. The tables report the results of separate regression analyses, estimating models using the "correct" variables (columns 1 and 2) and models using the "incorrect" variables (columns 3 and 4).

Table 3 describes the results of using socialization variables to estimate variation in community-oriented and self-oriented participation. Unstandardized coefficients are reported, unlike the path diagram, to make comparison across models possible. Our expectation is that the socialization model should do a better job of explaining columns 1 and 2 than columns 3 and 4. As reported in the path diagram in Figure 1, community-oriented participation in 1973 is chiefly accounted for by parent's community-oriented participation and by the respondent's parental status. There are no other direct effects. This is confirmed in column 1. Column 2 confirms that parental status in 1982 has an effect on voluntarism in 1982, net of the rate of voluntarism in 1973. Column 3, using the "wrong" variables to estimate variations in self-oriented participation in 1973 shows that parent's social participation has no effect and parental status is negatively related. Column 4 shows no direct effect of socialization variables on self-oriented participation, except for a very small (and uninterpretable) direct effect of parent's participation in 1973. The variance explained by the correct model (in column 2) is about four times that explained by the incorrect model (in column 4) using the unadjusted R^2s.

Table 4 describes the results of using status transmission variables to estimate variation in self-oriented and community-oriented participation. Columns 1 and 2 merely repeat the results of the path diagram, reporting unstandardized coefficients. They confirm the importance of education and income in both waves. The indirect effect of parent's education on 1973 voluntarism is not, of course, revealed in this table. Columns 3 and 4 demonstrate that status transmission variables are totally incapable of accounting for differences in community-oriented participation. The variance explained drops from 20% in column 2 to 1% in column 4. The correct model explains fifteen times as much variance as the incorrect model.

Conclusion

The study of voluntary association memberships has always had to deal with the problem that not all voluntary associations are alike. Previously, voluntary associations have been categorized as either expressive or instrumental, a distinction with its roots in the structural functionalism of Talcott Parsons. While it is undeniable that social organizations can either pursue goals that are primarily intended for members of the organization or are intended for the broader community (of which members are a part), we have argued that a more accurate rendition of this distinction would be self- versus community-oriented, where the first group of organizations seeks benefits and rewards for its members directly, while for the second group, any personal direct benefits members receive are incidental to the main mission of the organization, which is to meet a perceived community need.

Implicit in the debate over types of voluntary associations is the assumption that they represent different forms of social participation and are motivated by different concerns. A natural corollary of this, but one that has not been explored previously, is that each type of voluntary action has different roots. This is the major argument presented in this article. Human capital theories of voluntary association memberships are valid, but only with respect to the self-oriented type of voluntary association. In short, the theory works best at explaining precisely the kind of "voluntarism" where some benefit can be promised and calculated. This kind of voluntarism has familial roots, but they lie in the kind of human capital people inherit from their parents. Membership in this type of organization is a form of social capital more likely to be possessed (and passed on) by the wealthy and highly educated.

Human capital theories do a poor job, however, of explaining membership in groups where direct pay-offs cannot be calculated. Where the organization's rewards go to the larger community, voluntarism takes on a different character. Here, no amount of human capital inherited from parents seems to make a difference. This does not mean that parents are without influence. Rather, they socialize by example and even, as far as we know, by direct contact and recruitment to the group in question. These kinds of associations are much more endogamous, passed on from family to family. This finding is not surprising given that religious organizations are included, but note that these are not church affiliations, or preferences, but active memberships in church-related organizations.[5]

The data also confirm how important social integration is to certain types of voluntarism. Thus, membership in community-oriented organizations is quite strongly related to having children — an expected and natural finding. Having children is negatively related, however, to membership in self-oriented groups. No doubt the ties that bind are different in each case. In the case of community-oriented participation, social integration means ties to neighborhood, schools, parks, and similar places of collective consumption, principally through children. If this is self-interest, it is self-interest once removed, through one's children, and it is self-interest broadly defined, where the goods received are public and not private. In the case of self-oriented participation, the ties that bind are probably more narrowly conceived. They are principally occupational

and professional ties. The ties are those of production rather than consumption. If the first group of organizations is seeking to improve the circumstances of consumption (e.g., housing, streets, libraries, health care), the second group is seeking to improve the circumstances of production (e.g., pension benefits, safety rules, business contacts).

Distinguishing voluntary associations along the lines of self- versus community-oriented organizations also prompts a re-thinking of gender differences in voluntarism. It is widely reported that men have higher rates of social participation than women net of human capital variables such as education (Knoke & Thompson 1977). It has also been surmised that men are more likely to be active in "instrumental" associations and women more active in "expressive" associations. The assumption seems to be that men's traditional gender roles assign them a more public and women a more private social life. However, we found no gender differences in rate of participation in community-oriented voluntary associations. Women have as high a rate of participation in community-oriented associations as men. This suggests that women care as much about the public household as the private, that they have as public a role as men, albeit of a different kind, a role born of their frequent role as mothers. While they might be dependent in the role of the wife, in the role of the mother, they are all the things men claim to be — active, productive, strong, empathetic, and altruistic (Rossi & Rossi 1990). Just as noteworthy, we found no direct effects of gender on membership in self-oriented voluntary associations. Rather, women's lower rate of participation in this kind of organization is a result of their lower educational and income levels. Women do not participate as much as men because they lack the human capital and are perhaps not seen as desirable as men in the role of volunteer or board member.

Our results suggest that further research needs to be done on the age and life-cycle effects of community- and self-oriented participation. The table we present has a cohort gap between students and parents. More direct longitudinal evidence on community and self-oriented participation over the life course on the same sample would be more convincing evidence on this point. In effect, the table suggests that people move from liberal principles of self-interest at an early age when they need to establish a career to more communitarian principles of community orientation at later ages when they are building a community for their children. They may be more clearly altruistic when they continue to volunteer for community-oriented organizations after their children grow up and move away.

Notes

1. Hechter (1987:25) is correct in identifying this structuralist aspect to Durkheim's theory, linking it to the work of Simmel, and distinguishing it from the normativist perspective. However, his own characterization of it is highly individualistic: "structuralists usually consider solidarity to be the product of rational individual action" (25). In a footnote he dismisses the structuralists' focus on social networks because "it is not apparent how it can account either for the genesis or the transformation of these structures." We reject this argument and make the case that social integration is a concept of much value in the study of voluntary associations.

2. We recognize that a person may altruistically belong to a self-oriented voluntary association (e.g., an accountant from a CPA's association volunteering to do the books for the Red Cross). Also, a person may have selfish reasons for belonging to a community-oriented association (e.g., a person whose business involves producing braille books may belong to the Lions, who benefit blind persons). However, on balance, these are exceptions to the rule. Our explanation is not totally deterministic, but rather statistical. We further justify our division of organizations by the fact that the self- and community-oriented indexes are poorly correlated with each other, and that entirely different independent variables explain the two.

3. We also constructed a family status variable by combining responses to the marital status and parental status questions. This variable was coded one if the respondent was married with children and zero if the respondent was married without children, had children but was not married, or was single and childless. Using this variable rather than the parental status variable did not significantly alter the results of our analyses.

4. We give causal interpretations to variables such as educational level and parental status measured simultaneously since neither is "instantly" achieved. It is just conceivable, of course, that voluntarism is the independent variable in both cases. People who get involved in community-oriented organizations are more likely to become parents. People who join self-oriented organizations thereby boost their income (the connection to education is less plausible). These counter-interpretations cannot be ruled out. However, they are less convincing than the interpretations given here, and they ignore both indirect effects and the fact that prior voluntarism is being controlled for in each case. That is, both types of voluntarism are the result of an accumulation of effects, so that simultaneous variables do represent prior events.

5. Studies of intergenerational transmission of values have frequently assumed that parents have a more certain and lasting impact on their children if the relationship between them is close. However, Smith (1982) found that degree of affection between parents and offspring has little to do with how much they share educational goals. The Youth-Parent Socialization Study contains a question on how emotionally close to their parents students feel, in each of the three waves. Using this item, we created a variable to capture the interaction between parental example and closeness. But there was no relationship.

The Impact of Alcohol, Divorce, and Unemployment on Suicide: A Multilevel Analysis*

THOR NORSTRÖM, *Stockholm University*

Abstract

Sociologists have taken little interest in alcohol abuse as a possible antecedent of suicide. However, a theoretical link between the two phenomena can be postulated that is consistent with Durkheim's suicide theory. In this article, various data and methods are triangulated to scrutinize the relationship between alcohol and suicide. The control variables include, among others, divorce and unemployment. The empirical basis comprises ecological and time-series data for Sweden. Special efforts are made to integrate the findings with results from existent individual-level studies. According to the findings, a good third of the male suicides are attributable to the alcohol factor. The impact of unemployment is also found to be fairly strong, and here the indirect effects seem to be at least as important as the direct ones. No relationship was found between divorce and suicide.

The psychiatric and the sociological literature on suicide differ conspicuously in the role attributed to alcohol abuse as an antecedent of suicide. Hence, a large number of psychiatric and epidemiological studies single out alcohol abuse as an important risk factor in suicide. In contrast, the alcohol factor is not generally considered in sociological studies on suicide. For example, the word alcohol is never mentioned in Stack's (1982) extensive review of the sociological literature on suicide. The neglect of the alcohol factor is further indicated by the fact that out of a total of 3,610 references on suicide listed in *Social Sciences Citation Index* 1981-93, only 28 mention alcohol.

A possible explanation of this state of affairs is that Durkheim in his influential theory of suicide explicitly dismissed alcohol as a causal factor of suicide (Durkheim [1897] 1966:77ff). In a critical review of Durkheim's theory, Skog (1991) shows that this view is not unequivocally supported by Durkheim's own data. For instance, a closer examination of the data pertaining to the French departments reveals a substantial correlation between alcohol and suicide, contrary to Durkheim's inferences from these data.

I wish to thank Eero Carrol, Ole-Jørgen Skog, Rolf Sundberg, and two anonymous referees for advice and comments. Direct correspondence to Thor Norström, Swedish Institute for Social Research, Stockholm University, S-106 91 Stockholm, Sweden.

Many sociologists may find it natural that alcohol abuse, as well as its causes and consequences, are a concern only to psychiatry and related disciplines. It is certainly true that personality and biological factors create a broad range of individual variation in the risk of developing a drinking pattern that we would label alcohol abuse. However, if our focus is rather on changes in the prevalence of alcohol abuse in society, then a sociological perspective is much more fruitful. An influential theorization of this kind is the network approach to explaining alcohol abuse which has been developed by Skog (1985a). The point of departure of this approach is the fact that drinking behavior is social behavior; individual drinkers influence each other's drinking habits (although not necessarily symmetrically). This influence is not only mediated directly through face-to-face interactions, as observed experimentally in actual drinking situations (Bruun 1959; DeRicco & Garlington 1978), but also indirectly. Individuals' drinking behavior is affected by individuals in their social networks who, in turn, are affected by other individuals. As a matter of fact, large-scale changes in consumption need not depend solely on external factors, such as prices; they may also be produced by microlevel fluctuations that are synchronized by the operation of long-range indirect ties (Skog 1986). Thus there is a significant cultural dimension to the dynamics of alcohol consumption; much empirical evidence shows that various consumption categories, including heavy drinkers, move up and down the consumption scale more or less in concert (Skog 1985a, 1985b). A further implication of this is the existence of a close relationship between per capita consumption and the prevalence of heavy drinking and alcohol abuse (Skog 1985a). These phenomena may therefore be conceived as social facts in Durkheim's sense of the word.

Just as a sociological perspective is relevant for understanding the genesis of alcohol abuse, so can its consequences (including suicide risk) be approached sociologically. More specifically, it seems possible to postulate a theoretical link between alcohol abuse and suicide which is consistent with Durkheim's ([1897] 1966) well-known assertion that the suicide rate is inversely related to the degree of social integration. If by social integration we are here referring to the extent and quality of interpersonal relations, there is much to suggest that alcohol abuse has disintegrating effects. Some plausible mechanisms will be outlined here.

A meta-analysis of some thirty experimental studies reveals that consumption of alcohol tends to elicit aggressive behavior (Bushman & Cooper 1990). Situations that engender frustration seem to increase the likelihood of this response (Gustafson 1986). The aggressive behavior induced by alcohol may come in various forms and degrees, although most of the existent evidence concerns physical violence. There is thus a high incidence (typically above 50%) of intoxication among violent offenders (see e.g., Mayfield 1976; Roslund & Larson 1979). The relationship between alcohol and violence is also borne out at the aggregate level; a temporal relationship between alcohol consumption per capita and various rates of criminal violence has been established for several countries (Lenke 1990; Skog & Bjørk 1978). There is also documentation of less dramatic consequences of alcohol that are detrimental for interpersonal relations. On the basis of a population survey, Hauge and Irgens-Jensen (1986)

thus report a positive correlation between alcohol intake and the incidence of reckless behavior.

What has been noted above are alcohol-induced behaviors on the part of the heavy drinker that tend to dilute his or her social network. In addition, we may assume a hostile or disapproving attitude from society at large toward alcohol abuse which may worsen the prospects of heavy drinkers to become socially integrated. One piece of evidence in support of this notion is the following finding from a Swedish survey study (Kühlhorn & Ramstedt 1993). Out of a list including various minority and deviant groups (inter alia alcoholics, immigrants and criminals), the respondent was asked which of these persons he or she would not accept as a neighbor. It appeared that "alcoholics" was the least accepted category (indicated by 44%, followed by "criminals," 35%). Similar results are reported in a Danish study (Gundelach 1992).

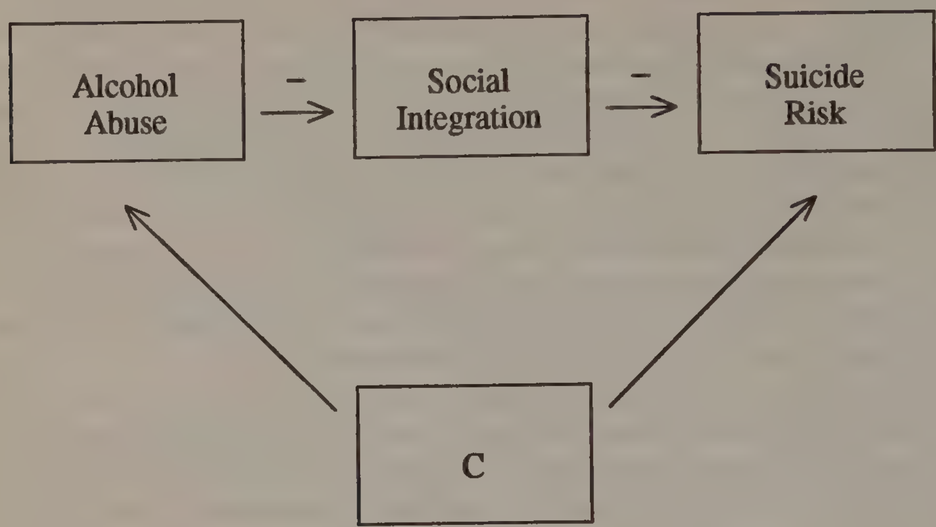
There are thus several reasons for believing that alcoholics and excessive drinkers are poorly integrated, having deficient social networks, which is also documented in the literature (Singer, Blane & Kasschau 1964; Straus & McCarthy 1951). It must be recognized that this may in part be the outcome of self-selection, in the sense that alcoholics have inferior capability for social interaction prior to the onset of alcoholism. However, a study by Philips (1976) indeed suggests that the progress of alcoholization is accompanied by a deterioration of social ties. In other words, the degree of estrangement increases for each stage of the alcoholization process. Two additional studies (Cahalan 1970; Cahalan & Room 1974) that explicitly address the temporal ordering between excessive drinking and complications with social relations also show that the former generally precedes the latter.

More direct evidence on the impact of excessive drinking on social integration and the suicide risk is found in Murphy's work (1992) which consists of detailed case studies of 50 consecutive alcoholic suicides in St. Louis (1968-71). A great majority (72%) of the subjects had little or no social support; relationships with spouses, children and friends were strained or terminated, and this was typically a result of the subjects' alcohol abuse. The fatality of this attrition of social support is indicated by the finding that one fourth (26%) of the alcoholic suicides had experienced an interpersonal loss in the last six weeks of their lives. This was "a last link to others /that/ had failed, generally as a consequence of the alcoholic's heedless disregard for its value to him or her." (Murphy 1992: 250.) The corresponding figure in an earlier study (Murphy & Robins 1967) is 32%, where it is also reported that such interpersonal loss was much less frequent among nonalcoholic suicides (3%).

The main feature of the above discussion of the link between alcohol and suicide is graphically summarized in Figure 1: Alcohol abuse tends to induce aggressive, reckless behavior that increases the risk of losing personal ties, i.e., leads to weaker social integration. This in turn, following Durkheim, increases the risk of suicide. To recognize the possibility of confounding influences, in Figure 1 C represents factors that are common causes of alcohol abuse and suicide risk, such as personality disorders.

The hypothesized association between alcohol and suicide is substantiated by a large number of epidemiological and psychiatric findings. Studies of individuals who commit suicide have repeatedly found a high incidence of

FIGURE 1: Hypothetical Model of the Link between Alcohol and Suicide



alcoholism (Beskow 1979; Robins et al. 1959). Further, several follow-up studies of alcoholics report grossly elevated risk-ratios for suicide (Dahlgren 1951; Nørvig & Nielsen 1956; Ritson 1977; Sundby 1967).

Since the prevalence of alcohol abuse is closely related to the overall level of drinking in the society (Skog 1985a) we should also expect an aggregate relationship between alcohol consumption and suicide. This is borne out in a growing number of studies. In an analysis of U.S. time-series data, Wasserman (1989) found that per capita alcohol consumption had a significant impact on the suicide rate. Also for Hungary (Skog & Elekes 1993), Norway (Rossow 1993), and Sweden (Norström 1988a) the effect of alcohol on the suicide rate is statistically significant and of approximately the same magnitude, while for Denmark the alcohol effect seems to be much weaker and detectable only in a time period with appreciable variation in consumption (Skog 1993; cf. Norström 1988a). A negative finding, with no significant alcohol effect, is reported for Finland (Norström 1988a).

Aim and Approach

Although the evidence presented above strongly suggests an association between alcohol and suicide, both the micro- and macrolevel studies conducted thus far have limitations. Findings from microlevel studies are compromised by the possibility of selection effects: alcoholics who commit suicide may already be at elevated risk prior to their drinking careers. The macrolevel findings, on the other hand, are always open to the objection of omitted variable bias. In this article I will triangulate various data and methods in order to scrutinize more

carefully the relationship between alcohol abuse and suicide risk. A number of other possible causes of suicide are included as control variables, which also makes it possible to assess the relative importance of the alcohol factor. The empirical basis of the study consists of ecological and time-series data for Sweden; in addition cross-level comparisons are made with existing individual-level studies. Since these studies pertain to men, the aggregate analyses are focused on the male suicide rate.

The rationale of triangulation is that a relationship that is supported by various kinds of data, analyzed by different methods, is more credible than a relationship that has been replicated several times, but by one method only. In the latter case there is always the risk that the finding is method-bound. When applying multiple testing under varied conditions, on the other hand, it is recognized that each test has its own weaknesses but that it is less likely that all tests are impaired by one common bias.

As already noted the major limitation of individual-level findings is the possibility of drift, or selection effects (Lieberson 1985). An essential comparative advantage of an aggregate effect estimate (whether obtained from time-series data or ecological data) is that it is expected to express the exogenous impact of the risk factor, net of selection effects (Norström 1988b). The rationale for this assertion is that the temporal variation of the risk factor (the effect of which is measured by the regression coefficient in a time-series analysis) should be due to changes in exposure and not to changes in self-selection. Analytically, this can be shown as follows. Consider the following micro model:

$$Y_{it} = C_i + \beta X_{it} + \epsilon_{it} \tag{1}$$

where Y_{it} is the response of individual i on the outcome variable at time t; C_i is the sum total of those unmeasured time-invariant attributes that are correlated with the outcome; and ε_{it} is a random error term. The potential bias in the estimation of β is due to the correlation between C_i and X_{it} that may arise because of self-selection. Now consider equation 1 in aggregate form:

$$Y_t = C + \beta X_t + \epsilon_t \tag{2}$$

As we can see the aggregation turns C_i into a constant which by definition is uncorrelated with X_t, and thus the source of bias is eliminated. To illustrate, let Y represent suicide, C personality disorders, and X unemployment. If personality disorders increase the individual's suicide risk as well as his risk of becoming unemployed, the estimate of β in the micro equation 1 will be biased upwards due to the selection effect. If we are willing to make the plausible assumption that variations in the prevalence of personality disorders at the aggregate level does not affect the unemployment rate, the estimate of β in the macro equation 2 is void of selection effects. (If this assumption is invalid, the estimate of β will be compromised by omitted variable bias.)

Thus both micro- and macrolevel studies have their weaknesses, but of different kinds. A micro finding that is replicated with macro data therefore gains in credibility from the fact that is not likely to have been produced by one common source of bias. However, strict comparisons of effect estimates from micro and macro studies are hampered by the use of different measures of association, typically relative risks and regression coefficients respectively. This calls for an impact measure that can be applied across different kinds of data,

and that can also serve our second purpose, namely to assess the relative importance of alcohol for suicide as compared to that of other causes. In research of the present kind, where the basic aim is to estimate a risk factor's effect on a specific form of mortality, such a standard is provided by an epidemiological measure: the attributable fraction (*AF*). It is usually calculated from micro data on the basis of two parameters: the relative risk (*RR*) and the fraction of the population (θ) which is exposed to the risk factor (e.g., Lilienfeld & Lilienfeld 1981:217):

$$AF = \frac{\theta(RR - 1)}{\theta(RR - 1) + 1} \qquad (3)$$

where the relative risk is defined as:

$$RR = \frac{\textit{Mortality rate for the exposed category}}{\textit{Mortality rate for the unexposed category}} \qquad (4)$$

The attributable fraction expresses the relative contribution of a risk factor to a specific cause of death — in other words, $AF * 100$ expresses how many percent mortality would be expected to decrease if the risk factor were eliminated.

The attributable fraction and the relative risk can be calculated on the basis of macro data as well (see Norström 1988b, for derivation of formulas). Consider a general macro model of the form:

$$Y = \alpha + \beta X + \epsilon \qquad (5)$$

where β is the unstandardized regression coefficient, *X* is the predictor (the risk factor), and *Y* is the outcome. Assume that *Y* is the mortality rate. The mortality rate produced by *X* will then be equal to $\beta * X$, and thus:

$$AF = \frac{\beta X}{Y} \qquad (6)$$

We may compute the attributable fraction for each unit of observation (i.e, each year if annual data are used) or for the average of *X* and *Y*. The measure is meaningful only if β is positive. The attributable fraction computed in this way has, theoretically, no upper limit. However, if a value exceeding 1 (or some other value that is implausible when compared with external information) is obtained, the estimate of β is evidently biased.

Given a semilogarithmic model (which will be applied in the present analysis) of the form:

$$Ln(Y) = \alpha + \beta X + \epsilon \qquad (7)$$

the formula[1] for the attributable fraction is:

$$AF = 1 - e^{-\beta X} \qquad (8)$$

To sum up, because different measures of association are so awkward to interrelate, cross-level comparisons seldom go beyond the sign and statistical significance of a relationship. However, by converting micro- and macrolevel estimates into a common impact measure (the attributable fraction), we can make cross-level comparisons more precise. Whether these estimates should be expected to be equal is something that must be determined in each specific case. In some instances, we may expect a discepancy between micro and macro estimates of effects. One reason for this is that micro studies generally focus upon the direct effect only of the risk factor, such as the effect of unemployment

on suicide risk. A corresponding macro study would relate the unemployment rate to the suicide rate, and the ensuing effect estimate would capture indirect effects as well, that is, the triggering of suicides among those who fear losing their jobs.

Other Correlates of Suicide

Although the focus of this article is on the relationship between alcohol abuse and suicide, it is of interest to assess the relative importance of alcohol compared with other causes of suicide. Another reason for including additional correlates that have been suggested in the literature is that we thereby reduce the risk of omitted variable bias. This is important particularly in the context of ecological data (Hanushek, Jackson & Kain 1974).

DIVORCE

Divorce is a central indicator of social disintegration considering the fact that the family is the most important primary group in our society. (Family integration was also the factor to which Durkheim devoted most space in his work on suicide.)

A large-scale study including individual-level data for 13 industrialized countries reports an elevated suicide risk among divorced persons in all these countries (Danigelis & Pope 1979). Furthermore, ecological studies (Breault 1986; Gove & Hughes 1980; Stack 1980; Trovato 1986) as well as time-series studies (Stack 1981; Trovato 1987) have found relationships between suicide and divorce (or living alone, in the article by Gove and Hughes).

INCOME

In his review of the research, Stack (1982) reports several macrolevel findings of an inverse relationship between income levels and suicide. Stack's interpretation of this is that "money reduces stress, makes life more worthwhile, and hence reduces the propensity toward suicide" (48).

RELIGIOSITY

According to Durkheim, religious belief protects individuals against suicide by means of its integrative effects in the form of shared beliefs and social ties. While Durkheim's hypothesis of denominational differences with respect to suicide has received little support in modern research (for an overview, see Stack 1982), religiosity per se appears to have an impact. In a study by Breault (1986), who also reviews other studies, religiosity proved to be a powerful predictor of the spatial variation in U.S. suicide rates.

UNEMPLOYMENT

The workplace is a vital locus of social ties and shared goals. To become unemployed means that these integrating forces cease to operate, which should increase the risk of suicide. A large number of aggregate-level studies of suicide have examined the role of unemployment and have generally found it to be significantly related to the suicide rate — for reviews, see Stack (1982) and Platt (1984). Of course, we may ask to what degree the aggregate relationship depends on the suicide response among unemployed persons — the relationship may also depend on reactions among other segments of the population, such as those who fear losing their jobs. However, microlevel evidence from several studies also suggests an increased suicide risk among unemployed people (Iversen et al. 1987; Moser et al. 1987; Norström 1988c; Platt 1984).

URBANIZATION

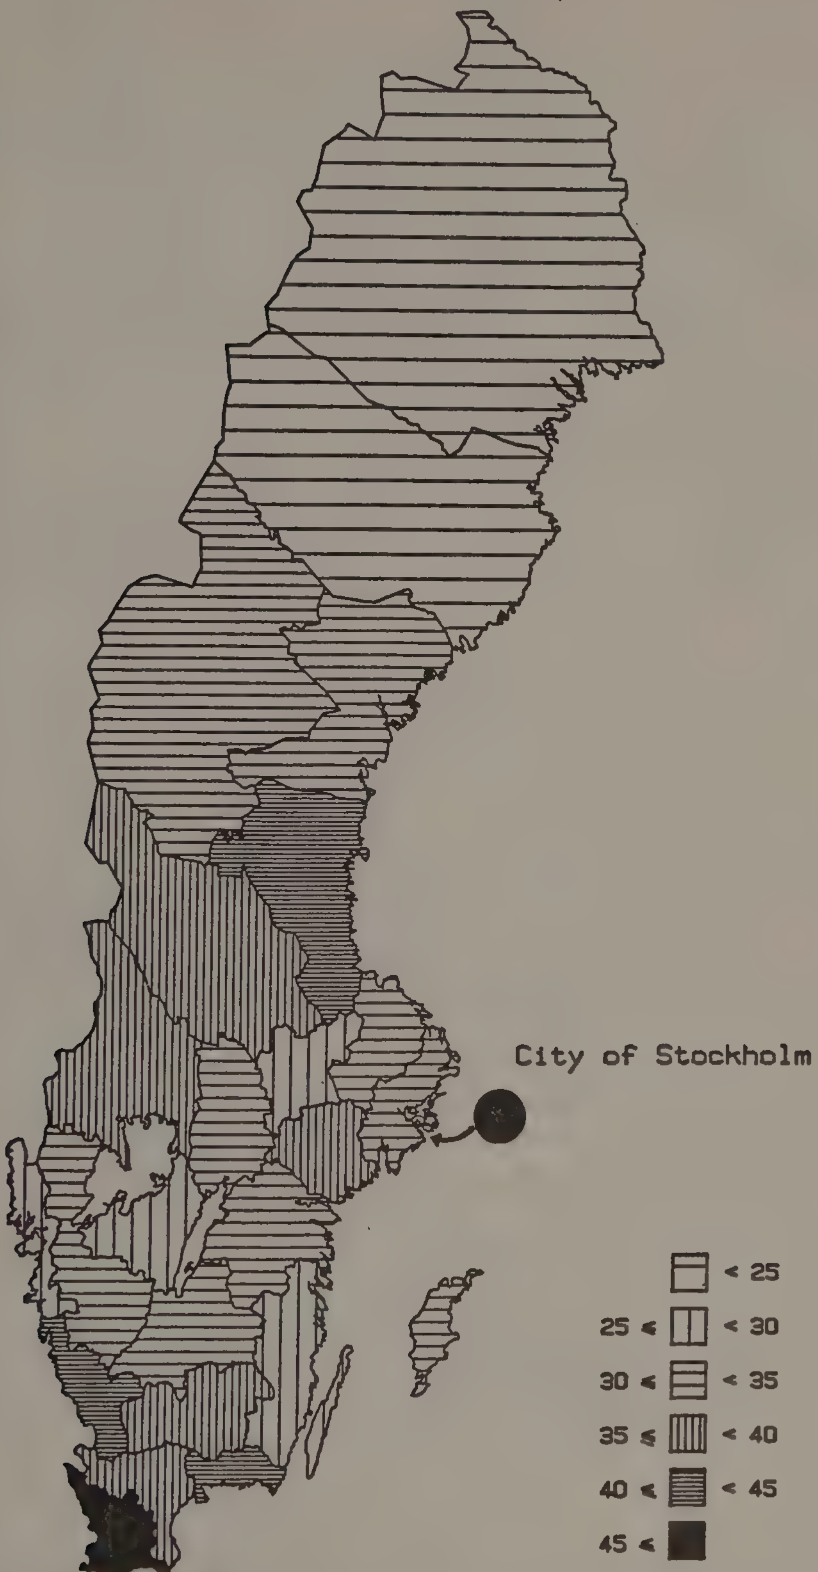
Due to cultural heterogenity and the influx of migrants, urbanized areas can be expected to have a higher degree of disintegration, which in turn should increase the suicide risk. Although the empirical evidence on the link between urbanization and suicide is somewhat inconclusive (see Stack's (1982) review of findings), it seems natural to include urbanization as a control variable in the ecological data.

The Ecological Data

The data points for the dependent variable consist of period averages of the age-standardized male suicide rate (1963-65) in each of Sweden's 24 counties and the city of Stockholm. The reason for averaging over a three-year period is to reduce the stochastic variation that is due to small absolute numbers. As detailed below, the explanatory variables are either averaged in the same manner, or refer to the midpoint of the study period. The delimitation of the study period was determined by the scarcity of county data prior to 1963. Data for more recent time periods are less feasible due to the new code that was added to the cause of death classification in 1969 (ICD AE 149): "uncertainty whether the death was accidental or intentional." A study by Bolander and Ettlinger (1980) suggests that a certain number of actual suicides is concealed in the new code, and that the use of it varies among regions, a fact of great significance in the present context. The ecological pattern of the suicide rate is thereby more affected by "noise" after 1968 which makes it less suitable for analyses.

The spatial distribution of the male suicide rate averaged over the years 1963 through 1965 is depicted in Figure 2. The highest rate is observed for the city of Stockholm (about 40% higher than the national rate), while the two northernmost counties score the lowest (about 50% below the national rate). There is no marked geographical gradient, however. We are still left with a related question: is the suicide rate spatially autocorrelated, that is, is there any tendency for proximate counties to exhibit similar rates? (See, e.g., Cliff & Ord 1973 for a discussion of spatial autocorrelation.) One way of determining this is

FIGURE 2: Male Suicide Rate, Swedish Counties, 1963-1965



to order the data pairwise, each pair consisting of counties with a common border, and then to compute the correlation within these pairs. Excluding the island county of Gotland, there are 48 such pairs. The resulting correlation is .18, which indicates that there is virtually no spatial clustering of this kind in the suicide rate. This may seem somewhat surprising; a cursory glance at Figure 2 gives the impression of some structure. However, closer examination reveals several cases of neighboring counties with greatly differing rates. This result is not only of descriptive value; the presence of spatial autocorrelation would have complicated the regression analysis (Cliff & Ord 1973).

In an analysis of the regional variation in the suicide rate, it is warranted to estimate the stochastic component of this variation first. It appears that the observed variance in suicides is about 16 times greater than should be expected by chance, assuming a Poisson process. (The difference is highly significant: $\chi^2 = 5{,}010.96$, 24 df, $p < .001$.)

We now proceed to the indicators of the explanatory variables.

Per capita consumption of alcohol (liters 100% per capita [15+] averaged over the years 1963-65) is used as an indicator of alcohol abuse. The rationale for this choice is the close association between per capita consumption and heavy drinking, or alcohol abuse, which has been documented in several studies (Skog 1985a, 1985b).

The divorce indicator is the percentage of men (15+) who were divorced (the stock) in 1964.

As pointed out by Breault (1986), the ideal measure of religious integration should include not only affiliation or membership, but also a more active component, i.e., degree of religious involvement and commitment. Such data are as unavailable for Sweden as for the U.S., and we must make the best of what exists. It should be noted that in addition to the State church, there are a number of Free Churches in Sweden (among which the Pentecostal Movement is the largest). Our measure should include both categories since they constitute alternative outlets for religious activity. However, membership in a Free Church reflects active religious affiliation while State church membership is a default option, with each citizen automatically a member unless he or she resigns (an option that few make use of). In light of these considerations, the proxy for religiosity to be used is an additive index comprised by (1) the percentage of the county population who were Free Church members, and (2) religious attendance in the State Church (measured as the annual percent average of the county population attending religious services). The index refers to the midpoint of the period under study.

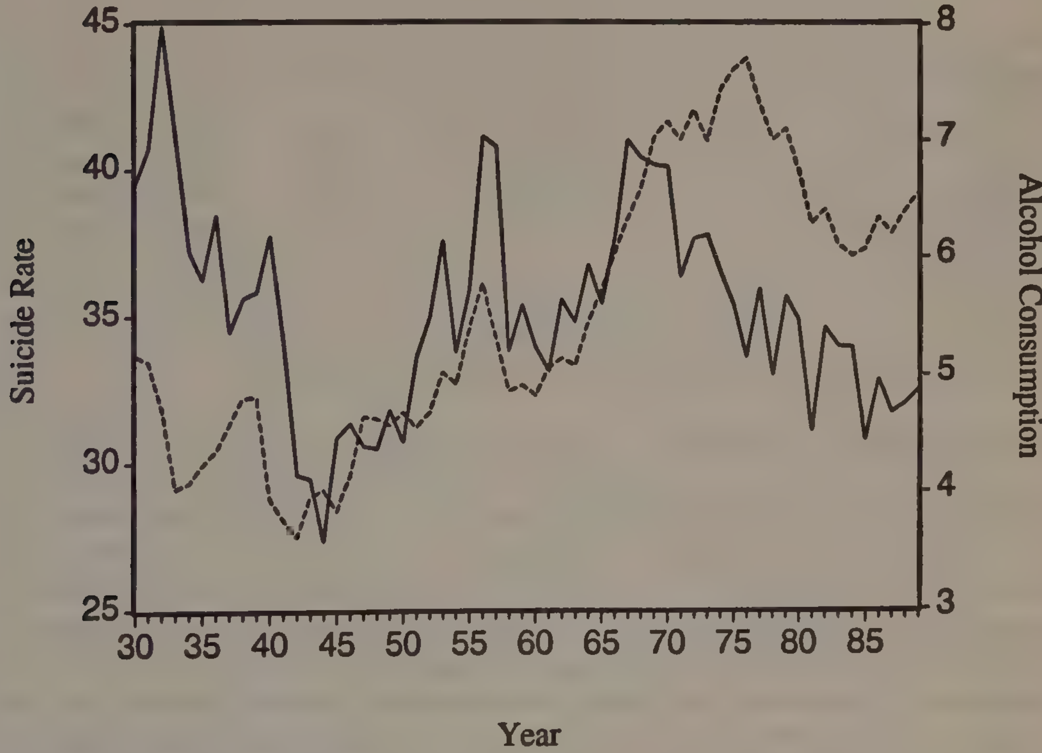
The unemployment measure (the percentage of the labor force who were unemployed) is averaged over the years 1963-65.

The urbanization measure (the percentage of the population living in densely populated areas) refers to the midpoint of the study period.

The Time-Series Data

Swedish time-series data are available for the following of the explanatory variables discussed above: alcohol consumption, divorce, and unemployment. These variables, as well as the suicide rate, are measured in the same way as

FIGURE 3: Male Suicide Rate and Alcohol Consumption (Liters 100%) per Capita, Sweden, 1930-1989[a]



[a] Male suicide rate — solid line
Alcohol consumption (liters 100%) per capita — broken line

their counterparts in the ecological data set. I also consider an alternative divorce indicator, the divorce rate (the incidence of divorces per 100,000 married men). In addition, the time-series data include a measure of real wages (for male industrial workers).

Figure 3 displays the suicide rate and the explanatory variable of primary interest here, alcohol consumption. Although the two series coincide fairly well, graphical evidence of this kind is not very weighty. Particularly when the data are nonstationary, it is crucial to difference the series before performing the analysis, so as to reduce the risk of spurious relationships due to common trends.

Analysis

This section first presents the analyses of the two aggregate data sets. Next, some findings from existent individual-level studies are presented. Finally, we

TABLE 1: Zero-Order Correlations between Male Suicide Rate and Five Explanatory Variables[a]

	X2	X3	X4	X5	X6	$\bar{X}$	Std. Dev.
X1 Ln suicide	.70***	.53**	-.62**	-.54**	.38	3.51	.24

* p < .05 ** p < .01 *** p < .001

observe to what degree the spatial and temporal results are consistent with each other, and how they compare with the individual-level data.

It seems likely that the role of our predictors in a suicidal process is of a reinforcing kind, amplifying the impact of each other and that of other suicidogenic factors. This would make a multiplicative model appropriate. Hence a semilogarithmic model of the following general form was used in the analyses of the ecological and the time-series data:

$$Ln\, S = \beta' X + \epsilon \tag{9}$$

where S is the age-standardized male suicide rate (15+), X is a set of explanatory variables, β is a vector of parameters, and ε is the error term.

ECOLOGICAL DATA

The matrix of correlations for the ecological variables (1963-65) is displayed in Table 1. We note that the suicide rate is fairly strongly correlated with most of the predictors; contrary to expectations, however, its correlation with unemployment is negative. The routine inspection of scattergrams revealed that this is due to an outlier (the county of Norrbotten which has a very high unemployment). This observation was therefore excluded in the subsequent analyses. (The correlation dropped in magnitude [to -.33] and became statistically insignificant [$p = .11$]).

It is further noted that the correlation between two of the explanatory variables, divorce and alcohol consumption, is quite strong ($r = .82$). This is at variance with existing microlevel data, which suggest a fairly weak individual-level correlation, in the range from .1 to .2 (Colett & Lindqvist 1971; Norström 1983). A plausible interpretation of this discrepancy would be that the individual-level correlation is compounded in the aggregation process by the geograph-

TABLE 2: Estimates of Semilogarithmic Model for Suicide[a]

[a] Estimated on Swedish County Data 1963-65. Ridge regression with k = .85.

ical allocation of people. Heavy drinkers and divorced people tend to live in the same areas, but they do not tend to be the same individuals.

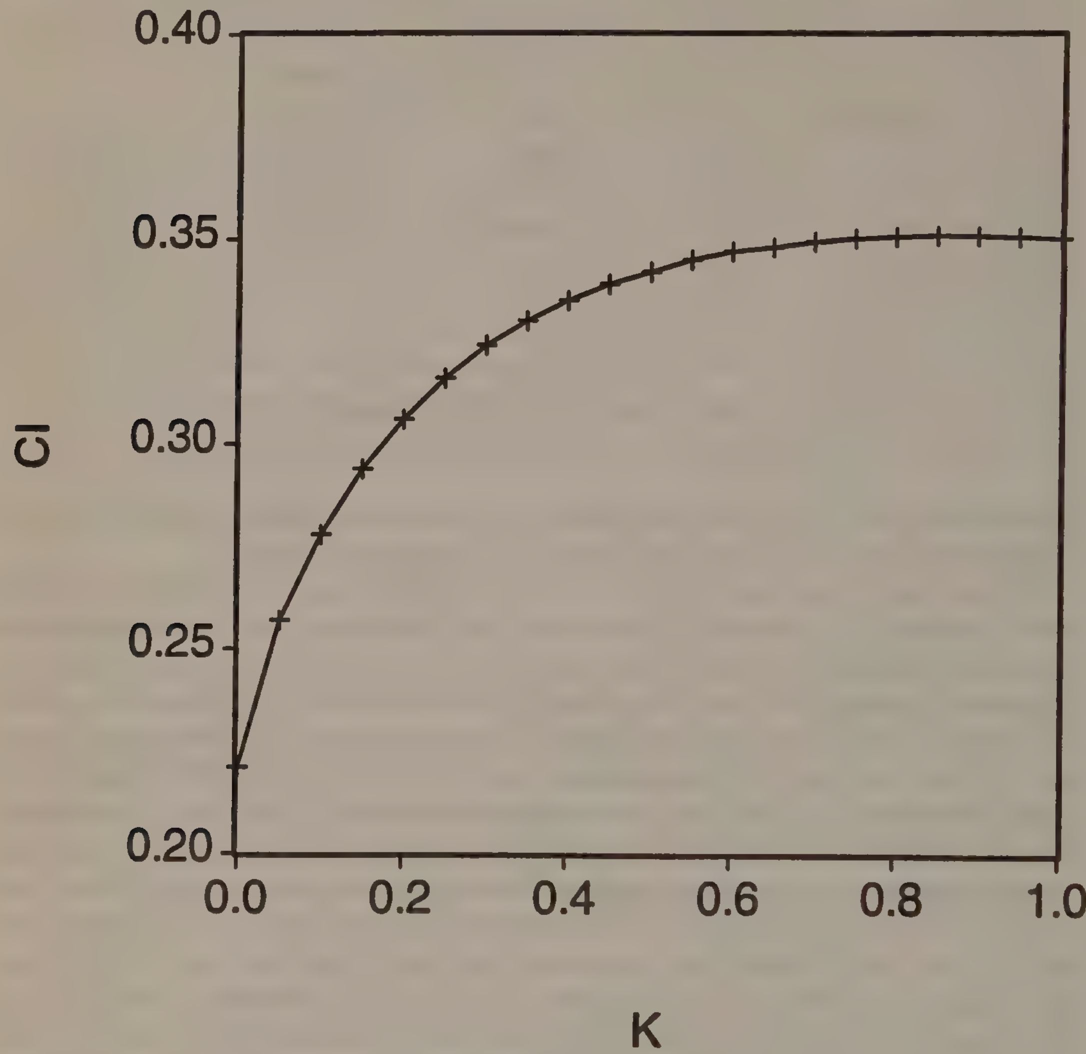
Since the strong correlation between divorce and alcohol consumption would present a problem in ordinary least squares (OLS) regressions, the alternative of ridge regression was applied instead. The idea of this method is to replace the matrix of moments (the $X'X$-matrix) with an $X'X$-matrix in which a constant, k, has been added to the diagonal elements. This is done stepwise, starting with $k = 0$ (which is equivalent to OLS). The loss from the bias thereby introduced is outweighed, up to a certain value of k, by the gain in decreased variance of the parameter estimates, which makes them more efficient and closer to the true values (Draper & Smith 1981; Hoerl & Kennard 1970). A cross-validation index (CI) is used to determine the optimal value of k (Stone 1974). This is constructed as follows: the model is fitted to the data set after deletion of a single data point. From the estimated model parameters we obtain a prediction $\hat{y}_{hi}$ for the deleted observation. The procedure is repeated for each data point, and then we compute:

$$CI = 1 - \frac{\Sigma(y_i - \hat{y}_{hi})^2}{\Sigma(y_i - \bar{y})^2} \tag{10}$$

CI cannot exceed unity but takes a negative value if the explanatory variables are irrelevant.

A semilogarithmic model (equation 9) was fitted to the data, and the ridge constant (k) was fixed to values between 0 and 1. Figure 4 shows the value of CI as a function of k. The problem associated with ridge regression of selecting a feasible value of k (Judge et al. 1980) does not seem very salient in the present analysis. As can be seen, the predictive power associated with OLS ($k = 0$) is much improved, and attains an optimum at $k = .85$. The ensuing parameter estimates are displayed in Table 2. (The coefficients can be interpreted as the percentage change in the suicide rate associated with a one-unit change in the explanatory variable.) It appears that alcohol consumption and religiosity are statistically significant, while the remaining predictors (divorce, unemployment, and urbanization) are much below significance.

FIGURE 4: *CI* as a Function of *k*



TIME-SERIES DATA

The method for analyzing time-series data that has been developed by Box and Jenkins (1976) has several features that render the estimates much more reliable than those that can be expected from ecological analyses. The risk of omitted variable bias is greatly reduced (although not eliminated) by the differencing technique; i.e., the analysis is performed on the yearly changes rather than on the raw data. In this way, linear trends are removed from the data. The rationale for this procedure is that an omitted predictor is more likely to be correlated with an included predictor due to coinciding or diverging trends, rather than due to synchronization in the yearly changes.

Another attractive feature of the Box-Jenkins method is that no assumption of independent error terms is necessary. The noise term (which includes explanatory variables not comprised in the model) is allowed to have a

temporal structure, which is modelled and estimated in terms of autoregressive or moving average parameters.

A semilogarithmic model (equation 9) was fitted to the differenced data for the period 1935-68, which includes the study period of the ecological analysis (1963-65). As a crude test of the presence of structural shifts — which would jeopardize comparisons between the time-series estimates and the ecological estimates — the model was estimated for a longer time period as well; 1930-89. A dummy variable was included to capture the possible effect of the new code (ICD AE 149) that was added to the cause of death classification in 1969 ("uncertainty whether the death was accidental or intentional"). The dummy takes the value of 0 before 1969, and 1 otherwise. The results are shown in Table 3. As can be seen, alcohol consumption and unemployment are statistically significant but divorce and real wages are not. The alternative divorce indicator (the incidence of divorce) also turned out to be statistically insignificant in both time periods, and did not alter the estimates of the remaining predictors (for the longer study period, the t value was -.82 [$p = .42$], and for the shorter study period 1.30 [$p = .21$]). It may also be noted that the differences between the period-specific estimates are negligible; there are thus no indications of structural shifts in parameters. The diagnostic tests of autocorrelated residuals are satisfactory.

INDIVIDUAL-LEVEL DATA

On the basis of microlevel data, it is possible to obtain estimates of attributable fractions with respect to suicide for the following factors: alcohol abuse, divorce, and unemployment.

Alcohol Abuse

There are three retrospective Swedish studies that provide information about the prevalence of alcohol abuse among male suicides (suicide attempters in one case). With material from the 1930s and early 1940s, Dahlgren (1945) found that about 47% of the males who had attempted suicide ($n = 94$) had received the psychiatric diagnosis of alcoholism. In the study by Beskow (1979), comprising 271 male suicides (1970-71), 44% were classified as alcohol abusers on the basis of register documents. The figures reported by Bonnichsen and Geertinger (1969), on 211 male suicides in the 1960s, are less detailed but compatible with Beskow's findings.

It is of course hazardous to draw causal inferences on the basis of the figures cited above; suicide as well as alcohol abuse may well have ensued from common personality factors. However, when reading the case histories of alcoholic suicides (e.g., Murphy 1992), one is struck by the common pattern of how alcohol abuse per se has created problems, or aggravated an otherwise troublesome life situation, with the result that the subject committed suicide. With the absence of alcohol abuse, one can envisage a nonfatal outcome in most cases. Nevertheless it seems quite plausible that the above-cited proportions of alcoholism among suicides are affected by self-selection. An attributable fraction (AF) of about .45 would thus be the upper limit of what should be expected.

TABLE 3: Estimates of Semilogarithmic Model for Suicide[a]

	1935-1968			1930-1989		
	Coeff.	Std. Error	p	Coeff.	Std. Error	p

[a] Estimated on differenced data for Sweden, 1935-1968 and 1930-1989.
Q = Test for residual correlation.

Divorce

According to Swedish suicide data disaggregated by marital status for 1966-1968 (Bolander 1972), the age-standardized relative risk of divorced men with respect to suicide is equal to 2.70 (computed according to formula 4 above). By applying formula 3, we obtain an *AF* equal to .041; about 4% of the male suicides would thus be attributable to divorce. In all probability, this figure is inflated by the divorced being selected with respect to characteristics that are linked to suicide.

Unemployment

A prospective study of unemployed men in Sweden (in the early 1960s) reports an age-standardized relative risk for suicide equal to 3.04, with an associated *AF* of .028 (Norström 1988c). In other words, about 3% of the male suicides would be directly attributable to unemployment. A prospective Danish study (Iversen et al. 1987) reports a relative risk of the same magnitude, 2.92. Since these risk estimates are based on prospective data they should be less vulnerable to selection effects.

The attributable fractions presented above capture only the direct effects on suicide of the risk factors alcohol abuse, divorce, and unemployment. As previously pointed out, the existence of indirect effects appears quite conceivable in some instances, i.e., effects on individuals outside the exposed population. A case in point is unemployment; an elevated suicide risk can be hypothe-

sized not only among those directly affected, but in addition among, e.g., individuals who fear losing their jobs. Contagion effects via social networks is another indirect mechanism that is likely to compound the detrimental impact of job losses (Eyer 1977). Impact estimates based on aggregate data include such indirect effects; a comparison between micro- and macrolevel findings would thus indicate the relative importance of direct and indirect effects.

COMPARISON OF FINDINGS

To what degree are the findings that have been presented above consistent with each other? As regards the alcohol effect, we note that the ecological and the time-series estimates differ very little; a one-liter increase in per capita alcohol consumption is expected to increase the suicide rate by about 10%. The attributable fraction associated with these aggregate findings is 37% (obtained by applying formula 6, and averaging over the ecological and the two time-series estimates). This is somewhat lower than the prevalence estimate of alcoholism among suicides (which was about 45%). The discrepancy suggests that the latter estimate not only reflects the impact of alcohol abuse on the suicide risk but in addition is influenced by self-selection.

The estimated effect of divorce on suicide turned out to be clearly insignificant both in the ecological and in the time-series analysis. It may be recalled that the microlevel evidence here suggested a little less than three-fold increase in suicide risk among divorced men, which implied that about 4% of the suicides would be attributable to divorce. Since this risk estimate is based on cross-sectional data, it is probably inflated by selection effects. The actual risk is thus likely to be even more modest; at any rate it does not appear to be strong enough to show that variations in the number of divorced noticeably affect the aggregate suicide rate.

The aggregate findings are more mixed when we come to unemployment; this variable proved to lack predictive power in the ecological analysis while it was clearly significant in the temporal analysis. Since the latter finding should be the more reliable one, we take it as the point of departure in the cross-level comparison. The attributable fraction that can be derived from the time-series estimates of the unemployment effect on suicide is equal for the two study periods, or .095. This is larger than what was obtained from the prospective micro data (.028). Although the difference should not be overemphasized, it supports the hypothesis discussed earlier of indirect effects of unemployment on the suicide risk.

Conclusions

In this article various data and methods have been triangulated to assess the impact on suicide of a fairly large set of factors, with the emphasis placed on alcohol abuse. To facilitate cross-level comparisons, an epidemiological effect measure, the attributable fraction, has been used. This synthetic approach provides a firmer basis for inferences and has the potential of giving insights about the links between the micro- and macrolevels.

The most unequivocal finding is that of the alcohol effect on suicide risk. Individual-level data, as well as ecological and time-series data yield fairly consistent estimates of this effect, which proves in all instances to be of substantial magnitude; a good third of the male suicides thus appears to be attributable to the alcohol factor. The impact of unemployment also seems to be fairly sizable, although it is substantially smaller than the alcohol effect. It is also less strongly corroborated since it was not sustained by the ecological data. A tentative conclusion here, based on the difference between micro- and macro-level estimates, is that the indirect effects of unemployment on suicide risk are at least as important as the direct ones. As to divorce, individual-level data suggested an effect on the suicide risk. However, this risk was fairly modest when considering the plausible presence of self-selection, and it did not materialize itself at the aggregate level. This outcome is not self-evident; in comparison, it was just noted that the similarly weak inividual-level relationship between unemployment and suicide seems to be compounded at the aggregate level by the operation of indirect effects. Why a similar phenomenon does not occur with respect to divorce is of course hard to ascertain; a possible explanation here is that increases in unemployment are more visible through media exposure and also more tangible due to experiences and discussions at the workplace.

Divorce receives a great deal of attention in suicide research, but our findings suggest that its importance perhaps needs to be reconsidered. Although divorce is a stressful life event, we should recognize that an unhappy marriage is socially and mentally depriving too, implying not only pains but also possible gains from divorce (Renne 1971). In one of the few well-designed studies that has some bearing on this issue (a panel study by Menaghan & Lieberman 1986), the estimated effect of divorce on depression is indeed quite weak (standardized beta = .08). When assessing the existent findings with regard to suicide risk, two qualifications should be borne in mind. First, the microlevel evidence is very likely to be affected by self-selection. In fact, Stafford and Gibbs (1988) found that the individual-level association between marital integration and suicide disappeared after control for other factors. Secondly, the available macrolevel evidence is not very convincing since the analyses typically are performed on trending raw data.

The remaining findings are based on single data sets, but may nevertheless be worth summarizing. Thus, religiosity turned out to be significant, and inversely related to the ecological variation in suicide, while urbanization did not have any predictive power. The same was true for real wages in the temporal analysis of suicide.

It is indeed thought provoking that sociologists studying suicide are so preoccupied with family and work integration variables, but almost totally neglect the alcohol factor. In contrast, psychiatric and epidemiological research has paid close attention to the role of alcohol abuse, supposedly because the diagnosis of alcoholism is so often encountered in the case records. This bias in sociologists' choice of suicide correlates can presumably be attributed to the Durkheimian legacy. Although there is nothing wrong in testing the specific factors that were propounded by Durkheim, deriving new ones from his theory may lead to additional insights. In my view, the alcohol factor is a case in point;

the hypothesis of a relationship between alcohol abuse and suicide fits well into Durkheim's theory of suicide, and it makes a substantial contribution to the explanation of suicidal behavior.

Notes

1. The derivation of formula 8 is as follows. Equation 7 can be written as (suppressing the error term):

$$Y = e^{\alpha} * e^{\beta X}$$

If X is set to 0, then $Y = e^{\alpha}$ Thus, excess in Y due to $X = e^{\alpha} * e^{\beta X} - e^{\alpha} = e^{\alpha}(e^{\beta X} - 1)$. Since AF is defined as the excess due to X, divided by the total, we have:

$$AF = \frac{e^{\alpha}(e^{\beta X} - 1)}{e^{\alpha} * e^{\beta X}}$$

$$= \frac{e^{\beta X} - 1}{e^{\beta X}}$$

$$= 1 - \frac{1}{e^{\beta X}}$$

$$= 1 - e^{-\beta X}$$

2. The occurrence of infrequent events, such as suicide, are normally assumed to be generated by a Poisson process (Feller 1950:153). In a Poisson distribution the mean and variance are identical (Hald 1952:714), and I therefore test by means of the Pearson chi square test whether the observed number of suicides in each county differs from the expected number.

White Male Suicide in the United States: A Multivariate Individual-Level Analysis*

AUGUSTINE J. KPOSOWA, *University of California, Riverside*
K.D. BREAULT, *Austin Peay State University*
GOPAL K. SINGH, *National Center for Health Statistics*

Abstract

Using data from the 1979-85 National Longitudinal Mortality Study and multivariate hazards regression analysis, the study investigates risk factors associated with suicide mortality among white males in the U.S. (ICD-9 Codes E950-E959). Results were mixed with regard to the social integration-suicide hypothesis. Divorced or separated men and those who live alone (socially isolated) have significantly higher risks of suicide mortality. However, single and widowed men do not have a significantly greater suicide risk after controlling for key social factors such as socioeconomic status (SES). The results also show that men who live in urban areas and those who are native born are at a higher risk for suicide.

Are marital status and social isolation related to the risk of suicide? In sociology, the question has almost exclusively been investigated at the aggregate level, with the finding that marriage and other sources of social integration reduce the probability of suicide. In psychology and research psychiatry, similar findings have been obtained at the individual level but with insufficient controls for key social variables (e.g., income, education, occupational status, etc.). There are no methodologically rigorous studies at the individual level in the sociology literature, and no studies in the psychological literature with proper social controls. Using data from the 1979-85 Longitudinal Mortality Study, we employ multivariate hazards regression to investigate risk of suicide at the individual level with controls for social integration, place of residence, age, nativity, education, occupation, and family income.

Theoretical Issues

While the theoretical underpinnings of this research are familiar to most readers, a brief statement may be in order. A long tradition in social thought, perhaps the most notable representative of which is Durkheim, has posited a relationship between suicide and social integration. Marriage and other social bonds are said to be protective against suicide, while the absence of social bonds is seen as causative of suicide. For example, in talking about egoistic suicide, Durkheim argued that married persons have lower suicide rates than singles and widowers. A truly vast amount of research has been done on the general social integration-suicide thesis (among the names most often cited in sociology are Breault, e.g., 1986; Danigelis & Pope 1979; Lester, e.g., 1983; Pescosolido & Georgiana 1989; Stack, e.g., 1982, 1985; Wasserman, e.g., 1984). Sociologists have generally supported the theory, but with few exceptions the research has been based on aggregates such as countries, states, standard metropolitan statistical areas (SMSAs), counties, cities, etc. On the other hand, psychological writers have generally produced the same results at the individual level, but they have done so without controls for key social variables such as income, education, and occupational status (e.g., Goldney 1981; Humphrey 1977; Robins et al. 1977; Shafii et al. 1985; Teicher & Jacobs 1966). The question we ask is simply: can the theory be sustained at the individual level when sufficient social controls are in place?

Two concerns led directly to this research. First, as mentioned above, the individual-level research in psychology and psychiatry fails to address key sociological variables, and second, there is evidence to suggest that the aggregate level findings in sociology may be artifactual (Breault 1995). Breault (1995) has shown that ecological correlates of suicide generally become insignificant once geographical region is controlled. Specifically, there appears to be no relationship between suicide and social integration in either the eastern or western region of the U.S., nor at the level of the state. Prior research findings were contingent on the east-west gradient in suicide and social integration (i.e., high suicide and low social integration in the west and vice versa). Such work cannot be regarded as conclusive because it is conceivable that national results may be correct even though regional and state-level results show the opposite (consistent findings from one level to another and, failing that, lower level results are the preference), but it raises the possibility that at the aggregate level suicide and social integration are fortuitously related. Because the issue cannot be adequately resolved at the group level, we must turn to the individual.

Note that, in contrast to the present research, Durkheim's work is at the aggregate level. There are those (beginning with Parsons) who argue that the study of individuals is irrelevant to Durkheim's theory. We see two problems here. First, as suggested above, the literature is at a point where definitive results cannot be obtained at the aggregate level (and this applies to purely aggregate-level hypotheses, that is, no individual-level predictions). Therefore, if we accept the traditional view, Durkheim's theory is now not falsifiable. Second, in this context Durkheim's views have not been fully understood. His primary interest is in a quantitative sociology in which theoretical ideas are

empirically adjudicated. His hopes were not for a sociology shielded from empirical scrutiny by the notion of aggregation, but the very opposite — a sociology that could compete empirically and triumph over other social sciences because of the superior truth value of its theory. Today, Durkheim would not sacrifice the scientific or theoretical status of his work in favor of a rigid allegiance to the aggregation concept. To do so would jeopardize his very notion of, and ambition for, sociology. For us to do so today only helps to isolate sociology methodologically from the other social sciences.

Materials and Methods

DATA

The data used for the study were drawn from the National Longitudinal Mortality Study (NLMS). The NLMS, a long-term prospective study of mortality in the U.S., was conducted by the National Heart, Lung, and Blood Institute (NHLBI) in collaboration with the U.S. Bureau of the Census and the National Center for Health Statistics (Rogot et al. 1992). The main objective of the project is to examine socioeconomic, demographic and occupational disparities in mortality in the U.S.

The public-use data file used in our analysis consisted of a cohort of five national samples from the Current Population Surveys between 1979 and 1981. Survival (mortality) experiences were studied until 1984-86 (NHLBI 1992). Data on mortality were collected by using the death certificate information available from the National Death Index (NDI), which were appended to the socioeconomic and demographic characteristics of the 1979-81 population cohort.

The NDI was originally designed to provide a simplified method of identifying the mortality experiences of participants in prospective studies. It is a centralized and computerized index of death records beginning with deaths in 1979 (Rogot et al. 1992). The NDI is maintained by the National Center for Health Statistics using information provided by state vital statistics offices.

The original study population for the NLMS comprised eight census samples numbering about one million people of all ages and races. The samples were mainly drawn from the Current Population Survey and are designated as "cohorts" for mortality follow-up. The individuals were known to be alive on the survey date and therefore eligible for follow-up with regard to survivorship from that date. Of the eight cohorts, seven were derived from the Current Population Surveys, and one was drawn from the 1980 census (Kposowa & Singh 1994; Rogot et al. 1992).

For purposes of this analysis, we considered only white males aged 15 years and older, because the number of suicide deaths among other race groups and women was too small to permit meaningful analysis. Note that suicide deaths among white males constitute nearly 75% of all suicide deaths that occur in the U.s. (CDC 1985). Moreover, suicide was the seventh leading cause of death for white males in 1989, but it was not among the leading causes of death for other race-sex subgroups of the population (NCHS 1992). The sample initially consisted of 203,437 white males which 216 had committed suicide by the end of the five-year follow-up.

VARIABLES

The dependent variable in the study was risk of suicide mortality. Deaths resulting from suicide were defined according to the Ninth Revision of the International Classification of Diseases (ICD-9), with the underlying cause codes E950-E959.

In estimating suicide risk, all those surviving beyond the five year follow-up period constituted right censored observations. Those who died of causes other than suicide during the five year follow-up period were also treated as right-censored.

The risk of suicide was modeled as a function of social integration indicators and other sociodemographic covariates. Specifically, the covariates employed included place of residence, age, nativity, education, occupation, family income, and social integration. Social integration was the main covariate in the analysis, and following Durkheim we used marital status and social isolation as proxies. Marital status was measured by a set of dummy variables, one each for single, widowed, separated, or divorced status. Those married at the beginning of the study constituted the reference category. Social isolation, as indexed by household size, was measured as a dichotomous dummy variable, with code 1 for those living alone and 0 for those who lived with at least one other person in the same household. We dummy coded our variables because our interest is on interpreting relative risks. The latter are much easier to interpret, more meaningful, and more intuitive when one compares subcategories of a variable to a reference group (Kposowa 1995; Kposowa et al. 1994:280).

The other covariates were measured as categorical variables, with percentage distributions shown in the first column in Table 1. Place of residence was measured by two dummy variables, one for SMSA, central city residence, and the other for SMSA, outside central city residence. Those who resided in a nonmetropolitan area represented the reference category. Age was captured by defining it in terms of a series of dummy vectors, one each for groups 25-34, 35-44, 45-54, 55-64, and 65 years and older. Individuals aged 15-24 years were treated as the reference category. Education was measured by two dummy variables, one for high school education and the other for 13 or more years. Individuals with less than a high school education constituted the reference group. Annual family income (1980 adjusted dollars) was indexed by three dummy variables, one each for $10,000-19,999, $20,000-24,999, and $25,000 and over. Those with family income of less than $10,000 were the omitted group. Occupation was represented by two dummy variables; one for those with nonprofessional occupations, and the other for the unemployed and those outside the labor force. Managerial and professional specialty occupations, coded 0, constituted the reference category. Admittedly crude, the professional-nonprofessional categories of occupational status are the only ones available with these data. Nativity was measured as a dichotomous dummy variable, coded 1 for native-born (those born in the U.S.). The reference category, coded 0, included the foreign-born.

THE STATISTICAL MODEL

The Cox proportional hazards model was used to estimate the effects of social integration variables on the risk of suicide mortality (Cox 1972; Gill 1992; Kposowa et al. 1994). The Cox model may be specified as,

$$h(t) = h_0(t)\exp(\Sigma_k B_k X_k) \tag{1}$$

where $h(t)$ is the hazard or risk of suicide mortality at time t, β_k are a set of unknown parameters to be estimated and X_k are K covariates. $h_0(t)$ is a baseline hazard function and is defined when all the covariates in the model assume the value zero. This model is called "proportional hazards" because for any two individuals at time t with hazards $h_i(t)$ and $h_j(t)$, the ratio of their hazard functions

$$\frac{h_i(t)}{h_j(t)} = \frac{h_0(t)\exp(\beta X_{i1} + \beta_2 X_{i2} + \ldots + \beta_k X_{ik})}{h_0(t)\exp(\beta_1 X_{j1} + \beta_2 X_{j2} + \ldots + \beta_k X_{jk})} \tag{2}$$

$$= \exp[\beta_1(X_{i1} - X_{j1}) + \beta_2(X_{i2} - X_{j2}) + \ldots + \beta_k(X_{ik} - X_{jk})]$$

is a constant, which may depend on the covariates, but not on survival time t (Singh & Kposowa 1994). The basic assumption of the model is that the covariates considered capture population heterogeneity, and that the hazard ratios remain unchanged over survival time.

Let T be a nonnegative random variable representing the elasped time from start of follow-up until the occurrence of suicide death. Note that the survival time, measured in years, as generated by each individual followed and each suicide, comprises the response variable in the present study, and it is inversely related to the hazard rate $h(t)$. In the case of the Cox model, the survival distribution function or survivor function of T, defined as the probability of surviving from follow-up to at least time t, is given by

$$=S(t) = Pr(T \geq t) = [S_o(t)]\exp(\sigma_k \beta_k X_k) \tag{3}$$

where $S_o(t)$ is the baseline survivor function representing the reference categories of the covariates. The proportionality of hazards was tested by inspecting the plots of $ln(-ln[S(t)])$ against survival time t for the various covariate categories, including those for marital status and social isolation. The plots were found to be approximately parallel, and hence the proportionality assumption was taken to be satisfied by the data.

The parameters in the hazards model as specified in equation 1 were estimated by partial likelihood using the PHREG procedure available within SAS (1991). The mathematical details of partial likelihood are discussed elsewhere (e.g., Allison 1984; Kalbfleisch & Prentice 1980; Namboodiri & Suchindran 1987).

Estimated relative risks were obtained by exponentiating the hazard coefficients ($\beta_k s$) in equation 1. Thus, the relative risk (RR) = $\exp(\beta_k)$. An RR greater than one indicates that the risk of suicide death is higher for the covariate category compared to the reference group. An RR of less than one has the opposite interpretation.

The statistical significance of the effect of each model covariate was assessed by the *t* statistic, obtained as a ratio of the parameter estimate to its corresponding asymptotic standard error.

Results

BIVARIATE ANALYSIS

In Table 1, we present the gross effects of each of the covariates on the risk of suicide mortality, adjusting only for the effect of age. We estimated a separate hazards regression model for each covariate to determine the crude but age-adjusted effect on suicide mortality. The estimated hazard coefficient (β) denotes the expected difference in the log of the suicide hazard between the covariate category (included in the model) and the reference group, controlling for age. Since β is somewhat awkward to interpret as the incremental net impact of the covariate on the log of the suicide hazard, we rely on the measure, $RR = \exp(\beta)$, to provide an intuitively more meaningful interpretation of the effect of the covariate on suicide mortality (Kposowa 1995).

For each covariate, the category showing an *RR* of 1.0 represents the reference group for comparison. The model chi-square (the likelihood-ratio statistic), which is a "global" test statistic for the whole model, was statistically significant at the .01 level for all models in Table 1, indicating that each of the covariates in the model significantly improved the fit of the model.

Most of the results in Table 1 are consistent with expectations concerning the relationships of the covariates and suicide mortality. As may be seen from the table, the risk (hazard) of suicide was 2.65 times as much for the divorced and separated as for the married. Moreover, being single was associated with significantly higher risk of suicide death. Compared to married individuals, the risk of suicide mortality was 61% greater among the single. Widowed status was not significantly related to suicide risk.

With regard to social isolation, persons living alone were more than twice as likely (2.36) to commit suicide than those living with others.

Consistent with results from some ecological studies, living in an SMSA (within the central city), is associated with a significantly higher risk of suicide than living in a nonurban environment. Specifically, the risk of suicide for suburban and central city residents exceeded that for nonurban residents by 20% and 48% respectively.

Compared to those aged 15-24 years, those in the 25-34 age group had a significantly lower risk of suicide. However, the relative risk of suicide was approximately 2.2 times as high for those 55 years and older as for those aged 25-34 years.

Although higher SES, as represented by education, occupation, and family income, was generally associated with lower risk of suicide, only those with family incomes less than $10,000 and those with more than $25,000 showed a significant difference in relative suicide risk.

The estimated relative risk for nativity shows a very strong effect of nativity status on suicide mortality. Those born in the U.S. experienced a risk of suicide that was 2.33 times as large as that for those born outside the U.S.

MULTIVARIATE ANALYSIS

Table 2 presents the net effects of marital status and social isolation on the risk of suicide mortality, controlling for the effects of the other covariates. Because they are highly correlated, inclusion of both marital status and social isolation in the same model reduces the importance of the two covariates. Those who are single, divorced, separated, or widowed are quite likely to live by themselves, whereas married individuals by definition are most likely to live with at least one other person. Therefore, in order to assess the net effect of marital status on suicide mortality, we estimated a hazards model that included all the covariates except social isolation (see model 1, Table 2). Similarly, to determine the net effect of social isolation on suicide mortality, we estimated a hazards model with all the covariates except marital status (model 2, Table 2).

As can be seen from model 1 of Table 2, when the potentially confounding effects of all other covariates were taken into account, the excess suicide mortality associated with being single, divorced, separated or widowed was significantly reduced. Compared to their married counterparts, those who were divorced or separated had a 136% higher risk of suicide. However, single and widowed status was not significantly related to suicide risk. For social isolation, while the net effect (2.16 — reported in model 2 of Table 2) was somewhat smaller than the gross effect (2.36) shown in Table 1, living alone still contributed significantly to higher risk of suicide in comparison to living with others.

Because young adults are less likely to be married, we eliminated those in the sample younger than 18. Significant differences did not obtain.

Finally, a full model incorporating all the risk factors (simultaneously controlling for marital status and social isolation), indicated that living in the central city of an SMSA was still associated with significantly higher risk of suicide mortality than living in a nonmetropolitan area. Specifically, compared to nonurban residents, those living in the central city of an SMSA were 50% more likely to commit suicide. This result can be taken as support for Durkheim's theory as many authors, (for example, Breault & Kposowa 1987) see the central city as less socially integrated than nonurban areas.

An additional finding that merits attention is that the native-born had significantly higher risk of suicide than the foreign-born. Even when all other covariates were controlled, nativity status remained a strong predictor of suicide mortality. Those born in the U.S. had almost three times as high a risk of suicide as the foreign-born. Future research may help to unravel the empirical association by differentiating the foreign-born by country of origin. It would be of interest to see if persons emigrating from countries with high rates of suicide exhibit especially low risk of suicide.

Summary and Conclusion

In sociology, previous research on the hypothesized relationship between social integration and suicide has been based largely on aggregates such as countries, states, SMSAs, counties and cities. Few sociologists have analyzed data at the individual level and fewer still have used rigorous methods. Moreover, there is

evidence that the prior aggregate-level research fortuitously linked social integration and suicide, that the relationship disappears once geographic region is controlled. In psychology, while there are several methodological concerns, the major problem is that researchers have failed to include important sociological factors such as SES. In the present study, using a national longitudinal sample of U.S. white males, and controlling for key sociological factors, we find mixed support for the social integration hypothesis: suicide is significantly related to married status in the expected negative direction and positively related to social isolation, but, in a direct contradiction of Durkheim, single and widowed status are unrelated to suicide risk.

Obviously, much more work needs to be done. In looking toward the future, we would invite other suicide researchers to join us on the frontier of individual-level studies. After all, as we have shown, our lives may depend on it.

Abstract

Stack and Gundlach (1992) tested and supported the hypothesis that the greater the air time devoted to country music in metropolitan areas, the greater the white suicide rate will be. We could not replicate this effect (Maguire & Snipes 1994), and Stack and Gundlach (1994) responded with a criticism of our methods, more specifically demonstrating measurement error in our construction of suicide rates. Here we show that this criticism sidesteps our most relevant critique of their study. Yet, we heed their advice, reattempt the replication using their own white suicide data, and still fail to produce a significant effect of country music on white suicide. Although the two are related bivariately, controlling for divorce, poverty, southern region, and gun availability results in a near-zero multivariate effect.

Following the recent wave of research on the relationship between culture and destructive behavior, Stack and Gundlach (1992) conducted a study of the relationship between country music and suicide. Analyzing data from 49 metropolitan areas, they found a significant effect of country music air time on white suicide rates, controlling for southern region, poverty, divorce, and gun availability. In a subsequent replication attempt (Maguire & Snipes 1994), we could not reproduce this effect, finding instead no multivariate association between the two constructs. Stack and Gundlach (1994) responded with a criticism of our methods. The purpose of this article is to readdress the issue, showing that — at least in Stack and Gundlach's sample of metropolitan areas — country music air time is unrelated to white suicide rates.

Stack and Gundlach have responded to our critique of their study on country music and suicide in an understandable fashion. They side-step our fundamental criticism (that their country music data does not come from the source it is supposed to have come from) and address an issue that is irrelevant (the definition of metropolitan areas). In their original article, Stack and

(N = 48)	

[a] In our original critique we used all fifty metropolitan areas for which country music were available. However, the WSR data provided by Stack and Gundlach contain data for only 48 of these locations.

*** $p < .001$. None of the other betas were significant at the .05 level.

Gundlach reported that their country music came from the 1985 *Radio and Records Rating Report*. We obtained this data from the source, and used it in all our analyses. Although this was the data listed in their references, we subsequently learned from them that *they did not use this data.* This comports well with our original suspicion that "the discrepancy may be based on a misrecording of the country music data" (Maguire & Snipes 1994).

In their rejoinder to our critique, Stack and Gundlach employ four measures of country music: (1) data from Maguire and Snipes, which is the exact data listed in their original article as *their* source, (2) *Radio and Records Rating Report* 1986, (3) Stack and Gundlach data, for which no source is listed, and (4) mean of 1985-86 data. The use of all these data sources is puzzling, especially since they did not really use the data listed in their original references. We have no indication of the source for the Stack and Gundlach country music data which they discuss in their rejoinder.

They address this issue only indirectly by arguing that "our" country music data is highly correlated with theirs. This does not, of course, mean that the various measures are interchangeable. For example, their country music data is correlated with southern region (a binary variable with *no* controversy in its measure) with a Pearson r of .26. The correlation between our country music and southern region, on the other hand, is .60.[1] Given that their primary independent variable has been inaccurately recorded, resulting in substantially

inaccurate correlations between it and other independent variables, it seems unnecessary to address measurement error in the dependent variable.

Stack and Gundlach argue that the contradictory findings between the studies is due to the discrepancy in the suicide rates. To show that this is not true, we simply substituted their suicide rates for ours and reran the model. After the substitution, the effect of country music remained insignificant. We found the same bivariate correlation between country music and suicide that Stack and Gundlach report in their rejoinder ($r = .46$); thus these data are not an issue in this analysis. Our results confirm our initial suspicion that there is no direct relationship between country music and suicide. Rather, as Table 1 shows, the relationship is spurious, attributable primarily to the effects of divorce and poverty, and to a lesser extent southernness and gun availability.

This is an *exact reproduction* using the *exact same data sources* of the model which Stack and Gundlach reported in their initial article. Because they questioned our critique on the basis of our white suicide rates, we simply replaced our rates with theirs (which they sent to us) and reran the model. They also pointed out that our control variables will be flawed to the extent that the populations in their denominators are not matched with the mortality areas. To correct for this, we took the area definitions sent to us by Stack and Gundlach, and calculated populations, divorce rates, and poverty rates, according to these mappings. As shown in Table 1, the effect of country music becomes insignificant when we introduce controls into the model.

Although we cannot speculate on why Stack and Gundlach, in their rejoinder, did not replace their country music data with ours (with which we provided them) and rerun the full multivariate model, it seems that this would have been the most convincing method of showing our original analysis to be faulty. Regardless of the ambiguity in *why* our analysis fails to replicate Stack and Gundlach's findings, this exchange has been important in showing how the smallest fluctuations in data measurement and analysis techniques can affect the conclusions of studies using small samples at the aggregate level.

Notes

1. This is for the 50 cities in our sample. For the 48 cities which are in both our data set and Stack and Gundlach's, this correlation is .57.

Country Music and Suicide — Individual, Indirect, and Interaction Effects: A Reply to Snipes and Maguire

STEVEN STACK, *Wayne State University*
JAMES GUNDLACH, *Auburn University*

Abstract

Previous work on country music and suicide has neglected individual-level data analysis of country music fans' suicide risk, use of an average annual country music exposure index, an analysis of indirect effects, and an assessment of interaction effects. The present article addresses these issues. First, country music fans are found to be at significantly higher risk of suicide than nonfans both in gun ownership and marital disruption. A significant zero-order relationship between country music and suicide does become spurious with controls when we use an average annual exposure index. However, country music exerts both indirect and interaction effects on suicide. Hence, the present article offers additional support for a link between country music and suicide.

First, we would like to employ some recently released, microlevel data that has relevance to the theory relating country to suicide. The debate over the country music subculture's impact on suicide had not used such individual level data to date. While content analysis of country music songs often suggests that country music fans may have elevated suicide risk to the extent that their life styles mirror the life styles found in the songs, there has been a dearth of empirical work on this central issue. For example, we found associations between country music and divorce, a known risk factor for suicide (e.g., Stack and Wasserman 1993). However, we had no microlevel data documenting that country fans were more apt to experience marital disruption than nonfans. Data are needed to document this association at the micro level of analysis.

Recent data from the General Social Surveys can be used to address this key issue (Davis 1993). In 1993 for the first time the GSS polled persons' musical preference. Some caution needs to be exercised in interpreting the results from these data since they are for 1993. By 1993 country's audience had grown and, according to our critics, had become more middle class in its orientation. Any

relationship between country and suicide risk factors may have disappeared, or become weaker, as a result, by 1993. Herein a country fan is defined as someone who responded that they like country music "very much." There were 248 such country fans and 632 nonfans in the GSS sample in 1993. Suicide risk factors are divorce and gun ownership. Divorce is defined as a positive response to the question: "Have you ever been divorced or separated?" Gun ownership is defined as the subject's reporting that they have a gun in their home.

Table 1 presents the data on divorce for country vs noncountry fans: 27.4% of the fans reported marital disruption as opposed to 18.4% of the nonfans ($\chi^2 = 8.85$, 1 df, $p < .003$). Country music fans are significantly more at risk of suicide on this suicide risk factor than nonfans.

Table 2 presents the data on gun ownership and musical preference: 61.8% of the country fans have a gun in their homes compared to 40.2% of the nonfans ($\chi^2 = 32.69$, 1 df, $p < .000001$). Country fans are at a significantly higher risk level for suicide compared to nonfans on this factor as well.

Given that country music fans are at higher risk of divorce and gun ownership than nonfans, we argue that country fans are also at higher risk of suicide.

Second, there is some confusion over the Radio and Records data on country music. Radio and Records publishes its *Rating Report and Directory* between two and three times annually. Estimates of country market shares are available for at least the spring and fall of each year. Snipes and Maguire (1995) seem to have the impression that just one estimate is available for each year. This is not the case. There are problems, however, in obtaining these data including the fact that the publication of these estimates is staggered (e.g., the Fall ratings for a given year come out in the next calendar year). Also, few libraries subscribe to the series and those that do typically discard old issues such as those giving 1985 estimates.

Probably the best measure of country's market share for 1985 is an average of the Spring and the Fall 1985 market shares data. We did not do this in our article (Stack & Gundlach 1992). We now have all the data (Radio and Records 1985; 1986). Taking the mean country market share for Spring-Fall 1985 as the measure of the strength of the country music subculture, the correlation between country and urban suicide rates is $r = .48$ ($p < .05$). This compares to an $r = .54$ in Stack and Gundlach (1992). While the difference in r's appears small, the relationship using the mean 1985 country market share could be spurious, as Snipes and Maguire (1995) correctly caution.

To address the issue of possible spuriousness, we replicated our model substituting the mean annual country music market share for 1985 as the measure of country music. We find that the significant zero-order relationship between country music and white suicide is no longer significant in this model.

Third, the idea, however, that country music has no effect on white urban suicide may be premature. Our model is overly conservative given that it focused only on direct effects. It is possible that country might be associated with suicide through indirect effects, as well as interaction effects.

Country music may have an indirect effect through its association with one or more of the predictor variables in the model. For example, given its preoccupation with the travails of love, it is conceivable that country might be

TABLE 1: The Relationship between Musical Preference and Ever Having Been Divorced or Separated, 1993

Divorced or separated	Country Fan (Percent)	Noncountry Fan (Percent)
Yes	27.4	18.4
No	72.6	81.6

$\chi^2 = 8.85$
$p = .00293$

predictive of urban divorce rates. Three fourth's of country hit songs dwell on themes such as marital strife and dissolution (Rogers 1989). This is important since divorce and suicide tend to be strongly related (e.g., Lester 1992). Taking the urban divorce rate as a dependent variable, we incorporated the remaining predictor variables as X variables affecting divorce. Country music had the strongest relationship to divorce ($\beta = .42$). Divorce, in turn, is the strongest predictor of suicide ($\beta = .39$). Hence, the indirect effect of country on suicide amounts to .42 x .39 or .16. Through its concern with marital dissolution and strife, it is conceivable that country music fosters divorce which, in turn, increases the risk of suicide.

Country music might also influence suicide through interaction effects with the other predictor variables. For example, in order for country music to have an impact on the urban suicide rate, perhaps it must be combined with an audience that is predisposed to suicide. A good candidate for such an audience would be the divorced population. That is, it would be in cities with both a strong country music subculture and a relatively large divorced population that we would anticipate a high suicide rate. Further, from the standpoint of a differential identification theory of deviance (e.g., Matthews 1968), it would be anticipated that divorced people would be precisely one of the most likely groups to differentially identify with the travails of love theme in country music. Divorced people would be the most apt to be receptive to the sad messages in such songs and be at greater suicide risk. For a further discussion of differential identification and suicide risk see Stack (1987).

To test a nonadditive model of suicide, divorce, and country music, we reestimated the model with a multiplicative term, divorce x country music. We used the mean level of country music for the year 1985 as the country music subculture estimate. Given multicollinearity between the multiplicative term and its components, only the multiplicative term was included in the equation, along with the measures of gun availability, southern location, and the structural poverty index. Controlling for the other variables in the equation, the divorce x country term was significant ($b = 0.02$, $t = 1.87$, $p < 0.05$). Cities that combine a high level of divorce with a high level of country music have an elevated suicide rate.

TABLE 2: The Relationship between Musical Preference and Having a Gun in the Home, 1993

	Country Fan (Percent)	Noncountry Fan (Percent)
Having a gun in the home		
Yes	61.8	40.2
No	38.2	59.8

$\chi^2 = 32.69$
$p = .00000$

Given that country music has both indirect and interaction effects that influence suicide, it is not correct to conclude that it is irrelevant to the generation of urban suicide rates. There are additional reasons for not dismissing the country music subculture from the etiology of suicide, and some further cautions as well.

Fourth, the relationship between country music and suicide needs replication for at least two reasons. The estimates of country music radio market shares fluctuate significantly enough from survey to survey to warrant analyses for other years in order to get more reliable results. Second, it is possible that given the increased popularity of country music over the last ten years, there is no longer even a zero-order association between it and suicide by the mid-1990s. What we found for 1985 may be a historically specific phenomenon. As the audience of country music shifts to a more middle class group with a lower divorce rate and generalized receptivity to the suicidal mood found in many classic country hit songs, it is anticipated that such songs would have less of an impact on such an audience. Indeed, such an audience could significantly change the content of country songs such that there might be fewer sad songs on the travails of love. These arguments are speculative and await a content analysis of country hit songs similar to the work of Rogers (1989) on 1,400 such songs from an earlier period.

Alternative measures of the country music subculture are needed in order to systematically explore the possible link between country music and suicide. For example country music magazine subscriptions could be used to this end, periodical circulation being another measure of culture (e.g., Baron & Straus 1989; Stack et al. 1994).

To the extent that the country music is stronger in rural areas, the study needs further replication. Our investigation was restricted to large urban centers. Perhaps the country music subculture would have a stronger impact on suicide where it is more dominant, that is, in rural areas.

Finally, it is also possible that the country music subculture fosters alcohol consumption. Lyrics in country often portray drinking as a normative response to stress in life (Chalfant & Beckley 1977). If so, that country may have still another indirect effect on suicide. An analysis that incorporates an index of

alcohol consumption is needed since alcohol consumption has a direct bearing on suicide risk (e.g., Stack & Wasserman 1993).

In summary, the analysis of individual level data connects being a country fan to known suicide risk factors, country has strong indirect affects on suicide, and country exhibits an interaction effect with divorce on suicide. It seems that the critics' notion of spuriousness in the country and suicide relationship is flawed.

Generally speaking, work is needed to explore the relationship between art and suicide, including country music. Elsewhere a relationship between heavy metal music subculture and youth suicide has now been documented (Stack, Gundlach & Reeves 1994). Possibly the rap music subculture might foster a high incidence of black youth suicide in urban areas.

Book Reviews

The Bell Curve: Intelligence and Class Structure in American Life.
By Richard J. Herrnstein and Charles Murray. Free Press, 1994. xxvi + 845 pp. $30.00.

Reviewer: FRANÇOIS NIELSEN, *University of North Carolina at Chapel Hill*

This massive but well-written study by the late Harvard psychologist Richard Herrnstein and public policy analyst Charles Murray is about the role of intelligence in the social structure of American society. Their discussion is organized into four parts. In part 1, they piece together a picture of the emergence of a cognitive elite in American society in the course of this century, through the increasing concentration of individuals with high IQ into the ranks of the educated elites and into high prestige occupations. This trend is driven by the reduced importance of social origin as the major factor of class distinctions and the increasing value of intelligence in the marketplace of modern industrial society, due to the increasing scale of organizations and markets combined with the intellectual demands of complex technologies and intricate regulatory structures. The authors view the cognitive elite as becoming increasingly separated from the rest of the population by a widening economic gap and increasing physical separation in the workplace and in residential communities. Through assortative mating, this process of "cognitive partitioning" is viewed as leading to the creation of a quasi-hereditary cognitive elite. This macrosociological description constitutes an updated and more richly documented version of the earlier work by Herrnstein (1973) on IQ in a meritocracy; sociologists will also find this discussion reminiscent, in a less fictional register, of the work of Michael Young (1958).

In part 2, Herrnstein and Murray present their own empirical analyses of data from the National Longitudinal Survey of Youth (NLSY), based on a longitudinal survey of about 12,000 youths aged 14 to 22 in 1979. Their analytical strategy is to estimate logistic regressions of a wide variety of dichotomous socioeconomic outcomes (dropping out of school, graduating from college, being in poverty, being unemployed, committing a crime, having a child out of wedlock, etc.), showing that in most cases intelligence, measured as the score on the Armed Forces Qualification Test (AFQT), has a stronger effect on the outcome than a composite measure of SES (based on family income and parents' education and occupational prestige). These analyses are carried out with non-Hispanic whites only, so issues of race or ethnicity are not addressed at this stage of the analysis.

Part 3 introduces issues of race and ethnic differences in IQ. The authors review the large literature showing the average IQ of blacks as being about one standard deviation lower that the white average, and the East Asian average (in the U.S. and abroad) as several points higher than the white mean. While maintaining a position of official agnosticism with respect to a possible genetic basis for these group differences in IQ, the authors suggest that the detailed pattern of the differences —

such as the systematic difference in intellectual profile between East Asians and whites, with an East Asian advantage concentrated in the nonverbal intelligence scores, and the finding that black and white scores differ most on the most *g*-loaded tests (i.e., those most related to a general intelligence factor) — strongly points to genetic roots. They go on to estimate the effect of IQ differences on average group differences in a variety of socioeconomic outcomes in the NLSY data. For many socioeconomic outcomes, such as family income and proportion below the poverty line, controlling for IQ substantially reduces the gap between blacks and whites. In some cases, such as wages, the discrepancy vanishes almost entirely when IQ is controlled. For educational attainment and access to professional occupations, however, the gap is reversed so that controlling for IQ, blacks have higher educational and occupational achievement than whites. This part of the book also discusses dysgenic effects of the higher rate of births among people of lower cognitive ability and the apparently contradictory phenomenon of the rise in average IQ that took place in industrial societies during the past few decades (the Flynn effect) and documents from the NLSY data the higher prevalence of low cognitive ability among people visited by a variety of social problems from dropping out of school to ever being interviewed in jail.

Part 4 deals with topics variously related to policy. The authors document the failure of many attempts to raise IQ. While better nutrition may play a role in the historical upward trend in IQ, formal schooling and special programs, notably Head Start, do not seem to raise IQ. Some highly intensive (and therefore costly) programs directed at young children, as well as adoption, might produce an IQ improvement. The authors credit affirmative action in higher education for opening college opportunities for more blacks and Latinos than would have otherwise been there, but spell out the downside of affirmative action programs in producing unfairness, distrust in the larger society of the achievement of minority students, and lowered productivity because of the suboptimal matching of ability and occupation. With respect to affirmative action in the workplace, they call for "scrapping the existing edifice of job discrimination law." In the penultimate chapter, the authors amplify their pessimistic view of a future "custodial state" in which an isolated cognitive elite (now merged with the affluent) protects itself in gated communities from the underclass at the bottom of the cognitive ability distribution, whose leadership has been drained and whose quality of life deteriorates further in the urban ghettos in which it is concentrated. The last chapter of *The Bell Curve* offers the authors' hopeful vision of an alternative society based on a return to the central role of local communities in which neighbors take care of each other, rules of conduct are made simple to understand and to follow, and everyone finds a "valued place" irrespective of their ability. This vision of vibrant local communities is hardly sinister, but the authors do not say how the devolution to local structures would happen, or even what trend might possibly lead in that direction. This exercise in utopia is largely independent of the rest of the book.

The Bell Curve has acquired its aura of controversy by challenging deeply held beliefs that make up the ethical-political credo of a large segment of the media and the public, including a large proportion of the sociological profession. While many people accept intuitively, at least in private, the notion that there is such a thing as intelligence, and that people differ in how intelligent or "smart" they are, the notion that part of the difference in intelligence among individuals might have a genetic basis is harder to accept, as it seems to imply a greater inevitability to the inequality in the distribution of ability than if cognitive ability were determined by purely

environmental factors that can be changed (it is hoped) through deliberate policy intervention. The idea that average intelligence varies among racial and ethnic groups, and that part of this variation might be genetic is the most scandalous of all. Although the authors do not claim to be certain about a genetic basis of group differences, they review the compelling circumstantial case for the existence of such a genetic basis, thereby committing the ultimate blasphemy against the dominant egalitarian social philosophy of our times. Many sociologists who already find such ideas disturbing as ordinary citizens may be additionally predisposed against attributing a central role to intelligence in explaining social organization by the preposterous notion that social facts should only be explained in terms of other social facts, so that intelligence — being a psychological, not a social, concept — does not constitute a legitimate sociological explanation of social reality.

Amidst the buzz and gossip that greeted the publication of the book in the fall of 1994, there was an almost palpable expectation of a critique that would deal the book a decisive blow by uncovering the "smoking gun," the irreparable defect that would invalidate the book as a whole and thereby save the conventional orthodoxy. Even highly competent reviewers in the social sciences have not discovered this fatal weakness, some contributing valid criticisms (e.g., Goldberger & Manski n.d.; Heckman 1995), others expressing their disagreement with little more than invectives (Hauser 1995). The task of hostile critics is made difficult by the fact that much of *The Bell Curve* consists of reviews of existing literatures, including the massive literatures on behavioral genetics and the psychometric properties of IQ tests. The authors' interpretation of these bodies of work is by no means outlandish: their summation corresponds by and large to a cautious and even conservative interpretation of the main thrust of the literature, for example in their working estimate of the heritability of IQ in the white population at .6, which is on the low side relative to current estimates in behavioral genetics (Scarr 1994-95). Many of the authors' conclusions such as those concerning the unbiasedness of IQ tests, the heritability of IQ, and the meaning of race and ethnic differences are widely accepted findings within the specialized literatures in which they originated. They appear novel and controversial only because the bulk of this research has been carried out away from the public eye and from the attention of many social scientists. The results of this research have been hidden in specialized journals, to emerge to collective consciousness only during brief episodes of intense public debate of the kind that greeted the work of Jensen (1969) or Herrnstein (1973). With scattered exceptions (e.g., Eckland 1967; Gordon & Rudert 1979; Scarr & Weinberg 1978), these findings have not been well disseminated in the sociological literature. It has been hard for critics of *The Bell Curve* to challenge convincingly the parts of the book that report well-established findings of sophisticated bodies of research.

The other main source of evidence used by the authors is their own analysis of the NLSY data. In a typical analysis, they estimate the coefficients of the logistic regression of a dichotomous outcome, such as dropping out of high school, on IQ, SES, and age (as a control for the dependence of the AFQT measure of IQ on age). They present the results of each regression graphically, by contrasting on the same graph the curve of the estimated probability of the outcome as IQ ranges from -2 to +2 standard deviations, with SES and age kept constant at their mean sample values, with the curve of the estimated probability of the outcome as SES ranges from -2 to +2 standard deviations, with IQ and age kept constant at their mean sample values. They show that, for many outcomes, the curve representing the probability of the outcome as a function of IQ is steeper than the corresponding curve for SES, and

conclude that IQ is a more important factor than SES in determining the outcome. As noted by some reviewers (e.g., Goldberger & Manski n.d.), this effective graphical presentation is equivalent to the use of standardized coefficients to compare the relative effects of independent variables measured in different metrics. While many sociologists would go on from here to estimate more complex models including larger sets of independent variables, the simple analysis serves well to reinforce the authors' central contention that IQ is a vastly better predictor of important aspects of social performance than SES, a variable that is the centerpiece of so many sociological explanations of such outcomes.

The larger scientific context in which the authors present their empirical findings is unusual, compared to many previous debates in the social sciences, in that the data they use are so publicly accessible. A CD ROM with the NLSY data can be obtained for a small sum, and many readers of this review can easily replicate the authors' analysis on their own personal computers. Social science research with controversial implications has rarely been as open and aboveboard as this, and one expects that many replications and extensions of the authors' analysis will appear in the future. The authors' analysis has been criticized on the grounds that the composite SES measure is unlikely to capture the entire childhood experience of subjects (which is a criticism of the concept of SES in general, not only the authors' use of it), and that their regression models are underspecified, in particular by not including education as an independent variable to predict other outcomes, since education could affect these outcomes independently of IQ (Heckman 1995). Some critics have also noted that the pseudo-R^2s that measure the fit of the logistic models are low for some outcomes. (The measure of fit is substantially higher for educational outcomes, such as dropping out of high school or graduating from college, and for some socioeconomic outcomes such as welfare dependency, than for the other outcomes analyzed by the authors.) Here also, critics are unlikely to find a smoking gun, because the strong effect of IQ that the authors find in their simple models is quite robust, as researchers familiar with the NLSY data know. No amount of nitpicking at the details of the authors' analysis is likely to obscure the remarkable fact that IQ, a measure of a psychological construct, is the best predictor of many aspects of the social performance of individuals many years later, with an effect stronger than any other of the traditional "background" variables including SES, certainly one of the sacred cows of sociological research.

While the major empirical findings of the authors are unlikely to be overturned, the book is not without weaknesses. As pointed out by Heckman (1995), the 875 pages of the book do not constitute a single coherent thread of argumentation, as some issues that are discussed at length by the authors, such as the question of the heritability of intelligence, are arguably separable from the rest of the issues; and the policy vision, particularly the rather romantic account of life in strong local communities, does not follow in any direct fashion from the evidence of the previous chapters. Occasional interpretations of current theories of behavioral genetics are incorrect, for example the discussion of the consequences of reducing the variability of the environment (p. 106), and other passages in which the authors exaggerate the intergenerational rigidity of cognitive classes based on genetic transmission of intelligence. Curiously, the same tendency to exaggerate the rigidity of genetic mechanisms — by downplaying the importance of regression to the mean — had already been criticized in the earlier work of Herrnstein (1973) by Eysenck (1973), who showed that genetic transmission entails much greater intergenerational mobility among IQ categories than Herrnstein had acknowledged.

A major contribution of *The Bell Curve* to sociological research is its polished presentation of the findings of literatures that have been by and large hidden from social scientists, including the behavioral genetics literature on the strong heritability of IQ, the conclusions of psychometric research on the absence of race (but not linguistic) bias in major IQ tests (Jensen 1980), the studies in the field of human resources of the predictive validity of IQ with respect to job performance, and the program evaluation literature revealing the failure of many intervention programs aimed at raising the cognitive ability of children. This skillful review, together with the wide diffusion of the book and the public attention that it has generated may help unravel the veil of collective denial that has shrouded knowledge of these issues in much of our field. With respect to the genetic basis of individual differences in cognitive ability, the book must also be viewed as part of the larger movement of ideas toward the rehabilitation of biological explanations and evolutionary approaches in the social sciences that has been discussed by Degler (1991). This emerging movement is associated with the discovery of a biological basis for many kinds of behaviors (including gender roles, Udry 1994), as well as the ascent of sociobiology (Nielsen 1994).

Sociology has a natural place to occupy within the scientific division of labor that would tackle the issues raised by Herrnstein and Murray, which is to focus on the aggregate consequences of the central role of IQ for individual outcomes demonstrated by them. Their analysis of processes of cognitive partitioning in modern industrial society in part 1 of the book is evocative but lacks formal precision, as it is pieced together from partial data and case studies with much extrapolation. There is a clear need to better document the existence of the mechanisms of social selection on the basis of cognitive ability postulated by the authors and integrate them with theories of social stratification. A special study under such a heading would include the possible role of cognitive partitioning on the upswing in income inequality that has taken place over the last 25 years. The possible dysgenic consequences of the negative correlation between fertility and IQ are another natural topic of study that is already being investigated by sociologists (Coleman 1993; Preston & Campbell 1993). Finally, in much sociological research on educational, occupational, economic, and behavioral outcomes of individuals, it will be harder than ever for researchers to ignore the importance of IQ as a potential explanatory factor with lame excuses about intelligence being a "psychological variable" and therefore off limits for sociologists.

Farm Security Administration Photographs of Florida.
Edited with an original essay by Michael Carlebach and Eugene F. Provenzo Jr. University Press of Florida, 1993. 124 pp. Cloth, $39.95.

Reviewer: AUGUSTUS BURNS, *University of Florida*

In no area of American society did Franklin Roosevelt's New Deal more radically alter the political and economic landscape than in the nation's farm life. The myriad programs that Congress and the President enacted, as Clifton Luttrell has remarked, "represented a new policy of government intervention in the business affairs of individual farmers. They marked a turning point from a free to a highly controlled economy." And the consequences of that policy shift have been the subject of a persistent and intense debate from the moment those policies were initiated.

The debate was joined in part by the very governmental agencies charged by Congress and the President to restructure American agriculture. Eager to persuade American citizens that farmers and farm workers were severely distressed — an easy case to make in the Depression years — the New Deal bureaus became their own advocates. In one such effort, farm policy administrators went into the picture business.

In 1935, President Roosevelt issued an executive order that created the Resettlement Administration, an agency intended to develop programs to assist farmers and their families who had been dispossessed of their lands (some of which dispossession had been accelerated by other New Deal farm programs, most notably the first Agricultural Adjustment Act).

To head this agency, Roosevelt named Rexford Tugwell, a Columbia University economics professor before becoming a member of FDR's New Deal "Brains Trust." Within a few months of beginning his duties, Tugwell had managed to offend nearly every segment of American agriculture, becoming a target of ceaseless criticism. In response, Tugwell launched a counter-attack, seeking to mute his critics by making a case for his policies directly to Congress and to the American people. He thus

employed Roy Emerson Stryker, formerly a Columbia University colleague to Tugwell, to assemble a group of photographers. Their mission would be, on government payroll, to document in pictures the plight of American farmers and farm workers — the agriculturally dispossessed. "Our job," Stryker noted in 1951, "was to educate the city dwellers to the needs of the rural population."

Stryker brought on board a team of genuinely gifted photographers: Carl Myradans, Walker Evans, Ben Shahn, Dorothea Lange, John Collier, Arthur Rothstein, Marion Post Wolcott, John Vachon, and Gordon Parks, a group that could form a nucleus for an American photography Hall of Fame. Predictably, they produced a photographic archive that was simply stunning in its technical quality and in its artistic construction.

One of the states where these photographers did much of their work was Florida. Much like California, Florida was a state where many people displaced from their farms in other parts of the South came to search for work and survival. They came in part because the depression years were a period of tremendous upheaval in Florida agriculture. The industry was essentially revolutionized into the agribusiness complex that became a vital part of the "new Florida." In the thirties, new farms of very large acreage were opened up in areas of the state previously little used for farming, most notably the area south of Lake Okechobee. Here up to 50,000 migratory workers might find work in peak season, often living in unimaginable squalor. Central Florida agriculture likewise grew substantially in the thirties.

The observable result of this boom in the midst of depression was a contrast of economic conditions that seemed almost medieval in its gross disparities. For Florida remained a tourist mecca to those people fortunate enough to be able to afford winter vacations from colder northern climates; and the operators who ran the large farms and processing plants survived the depression years in relative comfort.

In sum, the contrasts among the people in Florida was a socially conscious photographer's dream. Documenting rural poverty in Florida was a cinch, and the contrast with the manner of life in Palm Beach or other tourist communities made the economic differences even more striking.

In their superbly crafted work *Farm Security Administration Photographs of Florida*, Michael Carlebach and Eugene F. Provenzo Jr. have produced a book that faithfully reflects both the achievement and the craftmanship of the talented men and women who made these remarkable photographs. They have, in addition, produced a work that details in arresting visual images a "rural world lost," to borrow Jack Temple Kirby's phrase. Florida before World War II, before Disney, and all the other economic and political changes that have overtaken this semi-tropical sand bar, was indeed a different place. The ways in which it was different are too numerous to examine in a brief review. But as these photographs make clear, Florida was both more beautiful and more terrible, more promising and more forbidding. Clearly, the homogenization of space and structure that Daniel Boorstin identified many years ago as a product of modern America has nowhere occurred with greater impact than in Florida. To examine these pictures and to contrast them with modern Florida is to conclude that Joseph Schumpeter's phrase for industrial transformation — "creative destruction" — is a woeful understatement when applied to the "Sunshine State."

Carleback and Provenzo introduce their work with a very insightful essay that places these photographs in their proper historical context. They trace the evolution of Florida agriculture and the political circumstance out of which the Resettlement Administration (reorganized as the Farm Security Administration) came into being. They make clear that the photographs were in a sense essentially a political undertaking, intended to be used by the Roosevelt Administration to advance its

own farm agenda. And the discussion of these photographs is thus sensitive to the ongoing political disputes that accompanied them.

As pieces in a bitter political contest, these photographs have lost most of their partisan tone. The years since the New Deal have produced such extensive debate regarding the effect of New Deal farm policy that the photographs now are enveloped in that ambiguous legacy. What remains, the authors/editors write, is a historical and cultural artifact that also happens to be, collectively, a work of art. Both editors and the University Press of Florida are to be commended for the critical and production excellence that have combined to produce this exemplary volume.

Conditions of Liberty: Civil Society and Its Rivals.
By Ernest Gellner. Allen Lane, Penguin Press, 1994. Cloth, $27.95.

Reviewer: CHARLES KURZMAN, *Georgia State University*

The hypotheses in this book are thought-provoking, wide-ranging, and almost entirely unproven. Ernest Gellner compares four sociopolitical ideal types: premodern segmented society, civil society, Communist society, and Islamic society. He seeks to understand just how these forms differ, in their essences, and how they came to differ. This is a tall order for a short book, which gives the impression — a chatty manner and relative lack of documentation — of arising from a set of lectures. But Gellner's long experience as a philosopher and social researcher makes this a provocative new take on big thoughts in social theory.

Few theoreticians of the West's Great Transformation can draw on Ibn Khaldun's analysis of urban commercial society and tribal militarism. Few could make the analogy between Communist eschatalogy and the Islamic concept of Umma. Gellner's familiarity with Eastern Europe, both before and after 1989, allows him to note the widespread Soviet cynicism in the 1970s and 1980s about central tenets of Marxism: for instance, the "wry smile" of Soviet scholars passing a prominent red banner that quoted Lenin to the effect that "the teaching of Marx was all-powerful because it was true."

Gellner's argument, in short, is that civil society requires political centralization and socioeconomic decentralization. The centralization involves the building of nation-states with a monopoly on coercion — which Weber took as the definition of the state, but which in fact took centuries to accomplish. Only when this monopoly has been constructed, Gellner says, can segmented society — the localism of fiefdoms, tribes, and city-states — be overcome.

However, the creation of a nation-state does not necessarily lead to the flourishing of civil society. It can as easily lead to a Communist or Islamic social order. Islamic society, Gellner says, sacralizes everyday life, and subsumes economic to moral ideals. Gellner contrasts this image of the Umma — the community of believers, which punishes apostates with death, at least in theory — and a concept of "modular" individuals, analogous to modular furniture units, who combine and recombine easily into various agglomerations. Modern individuals do not need sacrificial rituals to mark their entry into a political party, and they are not accused of apostasy or treason for leaving. Although these agglomerations are not all encompassing, they are powerful enough to be binding on their members for short periods and discrete purposes.

Communism also undermines civil society by mandating a "secular Umma," in Gellner's phrase, in which public control of the means of production is intended to usher in a new form of liberated human relations. It failed not because of Stalinist excesses or Brezhnevian mismanagement — though the squalor of the Brezhnev

years hurt it more than the terror of the Stalin years — but because state control of the economy is necessarily fatal to civil society. Gellner makes the provocative argument that not only is Marxism totalitarian, but "under modern conditions, any totalitarianism will also inevitably be Marxist." It may not reproduce or revere Marx's philosophy *per se*, but it will plow under the capitalist economy in order to eliminate rival centers of power.

The main problem with comparisons of ideal types is knowing just when and where they apply. Does the concept of Islamic society refer to the official imposition of Islamic law, as in Iran, Pakistan, Saudi Arabia, and elsewhere, or to countries with secular-nationalist regimes and Islamic oppositions, such as (at this writing) Algeria, Egypt, and Turkey? It's unclear, even, why they should be lumped together as a single sort of society. Yet Gellner's great-books approach to the subject leaves off Islamic history in the Middle Ages, with Ibn Khaldun. His occasional references to contemporary Iran and Morocco don't give much guidance as to the referent of the ideal type.

The Communist ideal type is somewhat more credible. Gellner wrote this book while helping to establish the Central European University in Prague, so he spends considerably more time discussing Communism than Islam. However, Gellner's antagonism — he admits to having been fooled, once, by Communism's promises of economic progress — is insufferable. Gellner takes the collapse of Eastern European Communism as final proof of the failure of Marxism, and spends an entire chapter arguing that Marxist critics of the Soviet Union were just as wrong-headed as Marxist supporters of the Soviet Union. They maintained the ideal of a non-capitalist industrial society even after it was proven in all sorts of contexts to have disastrous totalitarian results. "*All* possible combinations seem to have been tried out in the course of an exceptionally thorough controlled experiment kindly arranged by history, and the verdict seemed much the same: Marxist societies ranged from the repulsive to the unspeakable."

Gellner fails to notice that Marxism has never come to power in the advanced industrial countries that Marx predicted — which makes Marx a poor prophet, maybe even a poor social scientist, but hardly disproves the ideal. Indeed, Gellner avoids discussing any recent Marxist theory, much of which is in fact concerned with the need for civil society. The book makes much of the Eastern European rediscovery of the concept of civil society in the 1970s, calling this a natural reaction to Communist totalitarianism. But Western Marxists made a similar discovery around the same time: the destruction of the life-world by the administrative-bureaucratic apparatus and the rejuvenation of civil society came to occupy a central place in the postindustrial and new social-movement analyses of Jean Cohen, Alain Touraine, Jürgen Habermas, and many others. None of this literature is mentioned in the book.

Finally, the ideal type of civil society does not sound much like any particular country we know today. The features Gellner stresses include: modular citizens, who are members of groups but not too strongly attached to any one group; a sense of moral obligation that forces individuals to honor their commitments willingly, not because of social pressure; cultural homogeneity within a given nation-state, involving the elimination of "semi-private and local" languages and idioms; and rationality, including "the non-conflation of issues, the separating-out of the social strands." This is all just a bit too smug, and it ignores the threats to civil society which exist in the countries where is it supposed to be flourishing. To take just one issue: the rise of the professions in this century has been accomplished in large part through the creation of semi-private idioms, barriers to entry, and complex initiation rites. What has been the effect on modularity, homogeneity, and rationality?

And what is one to make of socialist democracies and other hybrids? Ideal types do not meld easily on a continuous spectrum, and Gellner is unclear on the topic. In successive paragraphs, Gellner ridicules hybrids — "Either productive units do have genuine autonomy (in which case they behave as in the market), or they do not" — and then defends what sounds like a middle position, with some state control: "The unfortunate consequence of the collapse of the Marxist Umma is that it seems to some people, quite incorrectly, to constitute a vindication of the complete marketization of society, a reinforcement of the minimal state and maximal market doctrine. This is most unfortunate." Elsewhere he calls the lack of an effective welfare state "unutterably repulsive." So Gellner is not a radical free-marketeer.

The book's image of civil society, however, is purely capitalist. Gellner dates the concept of civil society to Adam Ferguson in the eighteenth century but ignores the changes that the concept has undergone in the meantime. Ferguson's definition of civil society equates it with apolitical, self-interested, individual behavior, as opposed to the martial passions of politics. Commerce, not virtue, constitutes citizenship. By contrast, nineteenth century theorists from Tocqueville to Durkheim saw civil society as something far more complex and difficult. The definition shifted to the presence of intermediary groups between the individual and the state, which capitalism could not be counted on to generate automatically. These intermediary groups could not be apolitical and individualistic — they had to be group-oriented and politically involved precisely in order to counterbalance the power of the state. Purely self-interested individualism was now seen as a threat to liberty, and not its savior.

Gellner recognizes that intermediary groups are necessary for civil society: "how is it possible to have atomization, individualism, without a political emasculation of the atomized man (as in the world of Ibn Khaldun), and to have politically countervailing associations without these being stifling (as in the [segmented, premodern] world of Fustel de Coulanges)?" Gellner's answer, already noted, involves the concept of "modular" citizens, who can be mixed and matched in changing combinations within a given nation-state (though not between them). Capitalism involves modularity, Gellner suggests, and therefore has no difficulty creating and sustaining intermediary groups. The only societies in the modern world that have to worry about atomization are Communist ones.

This is fairly unsatisfying. Gellner avoids all the tough issues raised by Tocqueville, Durkheim, and others: why should capitalism imply civil society? In terms of Gellner's ideal types, couldn't capitalism just as easily strengthen nonmodular social organization? Gellner briefly discusses the cases of East Asian industrialization and notes how capitalism is accompanied there by near-feudal paternalism. (The same might be said of post-Soviet gangsterism.) The book also notes that Islam has become more powerful in the past century, as Islamic countries have been integrated into world capitalism. Finally, the dog that doesn't bark: mass society. Gellner dismisses the doomsday capitalist scenario of isolated mass individuals, abjectly subject to totalitarian rule, that has motivated so many theorists since the 19th century. Indeed, Ferguson may be seen as a forerunner of this obsession, since he worried about the ability of commercial individualists to ward off military despots. Gellner tells him not to worry. As states have grown stronger and technologically more advanced, the economy grew stronger as well. Ferguson's pessimism "came to be invalidated . . . by the tremendous expansion of productive power consequent on the impact of scientific technology." The image is almost one of a benign arms race between capitalism and the state.

It is hard to conceive of large corporations as defenders of liberty, helping to stave off totalitarianism. Even Gellner has difficulty maintaining this image for long. One of the fortunate aspects of British industrialization, he notes twice, was that it

occurred during a period of "a fairly feeble technology," powerful enough to counteract the state but "blessedly feeble enough not to destroy society or its environment, or give anyone power to dominate society militarily. All that has changed, and will never happen again. Modern technology is enormously powerful, and contains a disastrous potential for ecology and for the possibility of terrorism, by generating devastating weapons controllable by a small number of persons."

The state, therefore, must protect us from capitalist destructiveness — "In a sense, it is still true that 'we are all socialists now'" — just as capitalism protects us from state domination. Without appearing to notice the distinction, Gellner wishes to defend both types of liberalism: the nineteenth century version which promoted the free market against premodern restrictions, and the twentieth century version which promotes state regulation and redistribution.

There is nothing inherently wrong with this form of argument: the balance of power between capitalism and the state may indeed constitute the "conditions of liberty" that the title seeks. But it is not the argument that Gellner wishes to make. Despite his defense of the welfare state, he feels that state subordination is crucial to liberty. He states this clearly in his discussion of Western civil society, where "wealth leads to power, more than the other way around. This is both remarkable and exceptional. Marxism made it into a reproach when it should be a source of pride, and it [Marxism] absurdly generalized the dominance of production over an alleged political 'super-structure' as a law governing all class-endowed societies, when in fact it is a unique characteristic of one type of society." The dominance of production over politics defines civil society and guarantees liberty. That seems to be Gellner's bottom line. It is, as Gellner says repeatedly of Marxism, only compelling to people who wish to believe.

The Costs of Privacy: Surveillance and Reputation in America.
By Steven L. Nock. Aldine de Gruyter, 1993. 149 pp. Cloth, $37.95; paper, $17.95.

Reviewer: KAREN A. CERULO, *Rutgers University*

I remember quite vividly, as a graduate student, spending significant portions of my days reading books like Chandler's *The Visible Hand* or Beniger's *The Control Revolution*. These were socio-historical accounts that focused us on those wondrous years at the end of the 1800s — a time when shores were joined by the cold metal of train tracks and worlds were merged by the vibrating signals of telegraph wires. The final years of the nineteenth century were all about possibilities, and when I delved into pages describing those years, I remember wondering if there could have been a more exciting time to be alive.

Recent technological advancements — fiber optics, satellite transmission, cellular radio technology, etc. — have silenced the query of my graduate school days. That "more exciting time" is here. In the world of cyberspace, possibilities abound. Virtual social realities afford the potential to eradicate distance, reforge social bonds, recast social roles, and more. Yet, along with these possibilities follow the inevitable prices. Steven Nock's book, *The Costs of Privacy*, addresses one of these problems, namely, the reconstitution of social trust.

Nock's argument is based on a triangular foundation that considers trust relative to privacy and "strangerhood." He defines the modern society as one increasingly characterized by anonymous actors who cherish their privacy. Under such conditions, Nock then explores the ways in which trust, an element so vital to the maintenance of social ties, is maintained. Among "strangers," trust cannot be maintained via traditional avenues of intimacy and knowledge of other. The answer,

for Nock, lies in the more formal mechanism of surveillance; surveillance allows for an informational basis of trust.

Nock initiates his thesis by charting the growth of surveillance relative to the growth of strangerhood and privacy. He pays special attention to the growth of one specific group of strangers so prevalent in current day society — those living in independent, non-family arrangements. Using this social group as a guide, Nock takes readers through two specific means of monitoring the stranger: the establishment of credentials, and ritualistic ordeals or tests of truth. The core of the book is devoted to "case studies" of credentials and ordeals: credit records, licensing, lie detectors, drug tests, and the like. His documentation regarding the rise and use of these techniques brings issues of social control, individual liberty, and exploitation to the forefront of the reader's attention.

The book's only flaw rests in the fact that it fails to pursue many of the most interesting issues that it raises. While the book documents the surveillance phenomenon, it offers little with regard to the implications of surveillance for various aspects of social interaction and social grouping. So, for example, while Nock notes that increased surveillance can be associated with decreased risk, he fails to speculate on the consequences of such a relationship for the groups it comes to characterize. Similarly, he notes that surveillance information will come to replace one's family of orientation in the construction of personal identity. Yet again, he is silent on the many interesting ramifications of such a shift — a shift that places empirical observation above subjective interpretation of self.

Despite these minor flaws, *The Costs of Privacy* is provocative, clearly written, and builds on timely and interesting events. It holds promise for researchers working in areas such as communication, community, culture, and technology. The book represents a useful addition to graduate seminars in these areas as well. Finally, it is written in an accessible manner, and could be added to advanced undergraduate seminar courses. All in all, social scientists should find this book worth reading; in addition, it could prove a catalyst to many stimulating discussions and research initiatives.

Old Nations, New World: Conceptions of World Order.
Edited by David Jacobson. Westview Press, 1994. 235 pp. Cloth, $54.95.

Reviewer: ALVIN Y. SO, *University of Hawaii*

In the introduction, David Jacobson points to two principal developments which contributed to the emerging world order by the turn of the twentieth century. First, there is the end of the Cold War, which has brought attention to national and regional differences, and the different conceptions and idioms of world order. Second, there is the process of globalization of issues like the economy, migrants, human rights codes, and ecological deterioration. As a result of this upsurge of transnational concerns, a wealth of domestic issues have been internationalized, and international and regional institutions have concomitantly become more salient.

The chapters of the book, then, analyze how the key states have changed their understanding of the emerging world order in the 1990s. Gilbert Rozman observes that Japan is groping for a more independent role with the end of the Cold War. Furthermore, Japan perceives that economic development, rather than military prowess, is the key to world prominence.

Samuel Kim points out the irony that China invokes Westphalian principles of national sovereignty in the post-Cold War world. Given communist China's

historical conflict with the West, it is surprising that she should draw on western ideas to protect her independence.

Stephen Chiu remarks that the dramatic economic growth of Hong Kong, Singapore, South Korea, and Taiwan was encouraged by the politics of the Cold War and the liberal international economic order. Subsequently, the post-Cold War world led them to pursue new strategies of industrial restructuring and outward relocation.

Under the conditions of the Cold War, Shlomo Aronson writes, West Germany sought to rehabilitate itself through economic growth. But the end of the Cold War has brought a complex choice. Will a united Germany remain obligated to its European and Western partnership?

George Thomas notes that in the Cold War era, the U.S. defined its moral obligation as spreading freedom and democracy as well as containing communism. However, the end of the Cold War resulted in the collapse of the containment strategy and made the American identity as a moral leader problematic.

Elizabeth Wishnick writes that more than a dozen new states have risen in the ashes of the Soviet Union, all trying to establish their own national identities and to define relations with each other and the rest of the world. Each of these states confronts questions about ethnicity, religious heritage, and models of economic development.

In the concluding chapter, David Jacobson contends that the system of sovereign states is in gradual decay. The end of the Cold War and interrelated structural changes have brought regional and international institutions to the fore. In particular, Jacobson stresses that international human rights legal codes are replacing national sovereignty as the basis for state legitimacy, and NGOs (Non-Government Organizations) have become the dynamic agents that propagate, reproduce, and interpret the premises of the international order itself.

This is a timely and important book. It is indispensable for any researcher who wants to find out the latest political and cultural development in key states. The chapters are all well written and of very high quality. Nevertheless, readers may wonder whether the world order in the 1990s is really new. Global economy, international migration, human rights issues, and environmental problems have certainly existed for a long time. Even the end of the Cold War may not be that novel, as it is just another cyclical shift from a "bipolar" pattern to a "multipolar" pattern in the world-economy.

So it seems premature to assert that the present system of sovereign states is in decay. First, even in the European Community, Shlomo Aronson points out that "the nation states are still present as economic framework that exist next to, and sometimes — in terms of power — above the international level." Second, while international human rights issues are getting more important, they surely are not replacing sovereignty and national self-determination, as seen by the fact that the U.S. quickly dropped human rights issues in return for more economic ties with China. Finally, financially dependent on key states, many NGOs have been de-radicalized and their orientation has shifted from "system-transforming" to "system-maintaining" (Samuel Kim's terms). Therefore, it is doubtful that the NGOs will become the dynamic agents to promote the new world order.

Governing Capitalist Economies: Performance and Control of Economic Sectors. *Edited by J. Rogers Hollingsworth, Phillippe Schmitter, and Wolfgang Streeck.* Oxford University Press, 1994. 316 pp. Cloth, $45.00.

Reviewer: GREGORY HOOKS, *Washington State University*

The contributors to *Governing Capitalist Economies* bring a variant of institutionalism to the analysis of economic governance. Each chapter is based upon a historical comparison of two or more nations. The contributors concentrated on one sector and did not attempt a sweeping comparison of the overall national pattern of economic governance. The case studies include: circuit boards in Japan and the U.S. (O'Brien); shipbuilding in Germany, Sweden, and Japan (Strath); machine tools in Germany and the U.S. (Herrigel); chemicals in several industrial democracies (Grant and Paterson); automobiles in Germany, Great Britain and France (Dankbaar); dairy in Austria, Germany, and Great Britain (Traxler and Unger); consumer electronics in Britain and France (Cawson); and securities in Canada, Great Britain, and the U.S. (Coleman). The editors' beginning and concluding chapters develop a (loose) conceptual framework and provided an overview of the volume. Despite the unavoidable centrifugal tendencies in edited volumes, the editors' conceptual framework is reflected in each of the chapters — to a greater or lesser degree.

The contributors build on recent efforts to synthesize economics and sociology. "The common premise throughout this book is that economic action is a special case of social action, and therefore, needs to be governed by institutional arrangements." Governance refers to a system of institutional arrangements — including rules and the enforcement of these rules — that regulates economic activities. The contributors are not only interested in identifying the institutions and the processes that serve to reproduce or transform them, they are also concerned with when and why institutional arrangements "work." In this effort, the contributors identify the stated goals of economic governance and examine the trends in market shares, profits, and innovation in the cases under investigation. The conception of institutions is broadened to encompass a variety of institutional forms that have appeared in the social sciences literature: markets and corporate hierarchies, informal networks, states, and associations (including private interest government). The collaborators do not put forward a grand theory that defines the relative importance and the relationship among these various institutional alternatives. Rather, they emphasize the variation in the presence, importance, and relationship among these institutions across nations and over time. The comparative case studies demonstrate that forms of economic governance are not determined by technologies, nor are they dictated by profit maximization strategies in any simple fashion. Rather, institutional arrangements emerge from the nation's political and economic history, and institutional inertia channels economic activity.

Those looking for a tightly woven theoretical framework applied to diverse cases will be dissatisfied with this volume. However, those seeking a focused but theoretically eclectic examination of historical cases of economic governance will find an interesting resource. In the tradition of Weberian "thick description," the case studies raise a number of puzzling theoretical issues, but offer few final answers. In fact, the most interesting insights were not driven by the theory, but instead were fortuitous aspects of relating the historical developments of the cases under examination. Although the editors discuss "convergence" theory — from its early postwar emphasis on the merging of capitalism and socialism to its current emphasis on globalization and declining sovereignty of states — that discussion does not offer a new theoretical synthesis. However, Coleman's examination of the securities industry in Canada, the United Kingdom, and the U.S. makes this issue

salient and interesting. His case study documents the manner in which the globalization of the securities market has overrun the distinctive governance regimes of these three Anglo-Saxon capitalist democracies — and suggests that the distinctive German and Japanese financial systems may soon confront a crisis of governance in this increasingly internationalized sector.

I recommend the book to those contemplating case studies of economic policies in the advanced capitalist nations. Those who would put forward a grand theoretical synthesis of economic governance would do well to read this book. One of the most important contributions of this book is its forceful reminder that history is messy and inefficient.

Forgotten Places: Uneven Development in Rural America.
Edited by Thomas A. Lyson and William W. Falk. University Press of Kansas, 1993. 278 pp. Cloth, $39.00; paper, $14.95.

Reviewer: RONALD C. WIMBERLEY, *North Carolina State University*

Flying across the U.S. at 35,000 feet is not a normal place to draft a book review, but it does provide a unique vantage for thinking about forgotten places and looking for them below. A couple of observations emerge. First, forgotten places are not just out of mind, they are mostly out of sight as well. Second, when they are spotted, they are all but lost in the vast rural space of our country's geography.

Lyson and Falk have not only found some forgotten places, they have found several rural social scientists to give us a close-up look. *Forgotten Places* is a contribution of the Rural Sociological Society's Task Force on Persistent Rural Poverty. It contains nine case studies on rural poverty with an introduction and conclusion by the editors.

The *forgotten* places brought into view by this book are actually *poor* forgotten places. And beyond the plane of forgetfulness and poverty, a third focus — rurality — rises to make the subject three dimensional and to show more clearly the "uneven development" of the socioeconomic terrain. Altogether, the forgotten places called to our attention are poor forgotten *rural* places.

Few of the forgotten places can be found in the central area of the U.S. Other than Appalachia, the Mississippi Delta, and the Missouri Ozarks, the rest are at the geographical as well as rural, social, and economic peripheries: in northern New England, Michigan's upper peninsula, the Black Belt South, the Rio Grande Valley, rural California, and the Oregon timber country. An example mentioned but unused is also near the border: the Indian reservations of the Dakotas.

My campus colleague Jim Clark asks why so much of North Carolina's rural poverty falls so near the state lines. Why so many poor forgotten rural places fall at the nation's borders is another good question, but one for another book. This book does enough already.

Lyson and Falk's introduction and conclusion provide, as usual, interesting reading. In what I think is an especially important chapter, Falk, Clarence Talley, and Bruce Rankin make the point that while rural areas tend to be poorer than urban areas, there is also inequality within regions between the Black Belt and the South, for example. "Those living in the Black Belt are more likely to have less education and lower incomes and to suffer from poverty and unemployment," and the economic gap appears to be widening. They conclude, "No part of the United States has been more forgotten or overlooked than the Black Belt." The inequalities of both rural residence and region, the authors note, make such places as the Black Belt "doubly disadvantaged."

Besides being the thesis of the Black Belt chapter, the multiple disadvantages of poor forgotten rural places become the major theme of the book. Other chapters describe how such disadvantages as poverty and rurality appear in other regions. In a rich and lucid chapter on California's rural communities, for example, Ted Bradshaw shows further disadvantages within rural places themselves. He sees a process of rural bifurcation where new, upscale, urban-based growth invades a rural area and forces the old, local, indigenous, rural population into worse conditions. The new development attracts attention; the old rural culture becomes less visible and more forgotten.

The book reveals more about America's poor forgotten rural places than one can observe from the vantage of a cross-country flight and costs quite a bit less. But whether you fly or not, don't forget the book. It's the rural binoculars that help to find and see the forgotten places.

Appalachia in an International Context: Cross-National Comparisons of Developing Regions.
Edited by Phillip J. Obermiller and William W. Philliber. Praeger, 1994. 238 pp. Cloth, $55.00.

Reviewer: ED KNIPE, *Virginia Commonwealth University*

This edited volume brings together several previously published works which compare Appalachia with similar communities and regions elsewhere.

In the introduction, William W. Philliber critically reviews several different approaches to defining the Appalachian region in particular and their implications for studying regionalism in general. Without so stating, the rest of this volume reflects those approaches within an international context. For example, the psychological basis of regionalism is illustrated by John Stephenson's comparison of "Shiloh," a community in North Carolina with Ford, a small community in Scotland. In both of these communities migrations are attributed to a search for what he calls "place," a search that reflects dissatisfaction with one's present residence. Susan Abbott compares school children in eastern Kentucky and Kenya on anxiety symptoms and gender expectations, which she concludes are similar because of similar community structures. Nelda K. Pearson compares the characteristics of community-based problem-solving groups in southwest Virginia and Newfoundland. She finds that these groups function differently as a consequence of the motives of "prime initiators" (those who founded the groups) and differences in Canadian and U.S. cultures.

Several chapters exemplify the economic approach to region. Graham Day compares Wales and central Appalachia as following parallel but somewhat different post-World War II histories of economic development. Richard A. Couto analyzes the antecedent conditions leading to the 1977-1978 coal miners' strike in Appalachia and the British miners' strike of 1984-1985. He suggests that both are the result of postindustrial conditions in these industries as measured by the rise of intermediate organizations that attempt to compensate for lost social overhead. The strike in both instances is a dramatic expression of that loss. John Gaventa traces the movement of a single industry — a seat belt manufacturer — from Michigan to Knoxville, Tennessee, then to Alabama and finally to Mexico to assess the negative impact on workers in Knoxville. Benita J. Howell argues that the stereotypical view of Appalachians as "backward" is not an isolated phenomenon. Such views of various populations may indeed be universal and may have their roots in economic ties between a region and the larger social and cultural matrix within which it is found.

Although not directly related to analytic disputes concerning definitions of a region, several chapters focus on attempts to ameliorate "problems" associated with Appalachia. For example, Richard A. Couto paints a rather dismal picture of the future for a deindustrialized and postindustrialized America based on what has happened and is happening in Appalachia. His argument rests on defining the region in terms of labor and the kinds of work that mark a shift from an industrial economy. Glenn A. Mitchell compares Catalonia and Appalachia on the basis of what he calls "minority regions" and finds that differences in development are the consequence of historical variations in political and cultural characteristics of each region. Phillip J. Obermiller compares regional planning organizations in southern Italy and Appalachia. Assuming Appalachia is a region, he argues that both areas have failed to improve the conditions for which they were organized and suggests that grassroots efforts are the only way these regions can be developed. And finally, Peter R. Sinclair reviews several theoretical models that have been used to understand regional inequity in Canada. He specifically focuses on the maritimes as his most inequitable regions, but fails to mention Appalachia.

While each chapter offers interesting insights into Appalachia, the book needs a summary chapter to find those common threads that tie these disparate studies together. The failure is annoyingly common in books of readings. I think of a book as a tool, the usefulness of which is reflected in a good index and bibliography. While this index is adequate, many of the references cited in the text could not be found in the bibliography. For serious scholars this omission can be maddening.

Relations into Rhetorics: Local Elite Social Structure in Norfolk, England, 1540-1640.
By Peter S. Bearman. Rutgers University Press, 1993. 216 pp. $40.00.

Reviewer: RICHARD LACHMANN, *State University of New York at Albany*

This is a book which you might want to give to your historian friends since it presents sociology in the best possible light. Bearman addresses the most intractable and the most written about issue in English historiography: the question of why country-based gentry sided with Parliament or with King Charles I in the English Revolution and Civil War of 1640-1649.

This question has driven many contemporary scholars to the point of despair. A group of prominent revisionists now declares that, because people had various reasons to choose sides and even more reasons to ally with both sides or try to remain neutral in the Civil War, that conflict is beyond understanding. Bearman cuts through such antirationalist defeatism. Bearman, like the revisionists, considers the simple Marxist class analysis of the Civil war "clearly wrong." One response to that failure has been to draw ever finer distinctions among class fractions in hopes of finding specific "categorical affiliations" which could predict action. Another direction, favored by the revisionists, has been to examine the individual biographies of participants in the Civil War in hopes of identifying idiosyncratic rather than categorical bases for actions.

Bearman proposes another, specifically sociological, strategy. He sees "structural equivalence of individuals in social networks," rather than common attributes, as the bases for interests and actions. He uses blockmodels to go beyond the revisionists' concern with individuals' particular social relations and to aggregate "individuals with similar patterns of social relationships into an equivalency class." Network analyses allow him to test the saliency of different social factors, identified by Marxists and others, as the bases for action in each historical era.

The blockmodel analyses reveal that kinship in the sixteenth century and religious patronage in the decades leading up to the Civil War were far more important than the usual factors emphasized in historical research on the Civil War — land holdings, religious identity, officeholding, connections to the royal court, and residence in counties — in determining social and political identities among the ruling elites of Norfolk. (Bearman's analysis is confined to the county of Norfolk; however, he is exemplary in identifying Norfolk's peculiarities and in explaining the extent to which his findings can be generalized for the rest of England.)

Kinship determined political affiliation until the late sixteenth century, when it declined as the principal organizing relationship in Norfolk. Kinship lost importance when and where the crown succeeded in breaking the key magnate dynasties around which kin blocks were organized. At the same time gentry excluded from magnate blocks sought status and power by marrying outside of Norfolk, further reducing the cohesive and stratifying force of kinship.

State formation was a result of the efforts of gentry from below to gain status as well as the strategies of monarchs from above. The gentry sought royal favor both for financial advantage and to replace magnate-centered kin networks as an organizing basis of county politics. The crown's generous granting of favors shattered magnate authority but at the cost of surrendering control of future patronage decisions to factions organized from the counties. Such factions did not provide clear bases for stratification within counties. Bearman describes institutional paralysis on the Norfolk Commission of the Peace (the county's main governing body) during the first decades of the seventeenth century.

Norfolk gentry overcame status and political confusion through the use of religious patronage. Gentry came to hold a majority of advowsons (the right to appoint parish ministers) in the aftermath of the Henrician Reformation. Spurred by Puritan zeal, a minority of gentry started using advowsons to control the ideology of ministers rather than just to profit from parish revenues as had most gentry in the late sixteenth century. Orthodox and Catholic patrons responded with ideological appointments of their own. Networks of gentry linked through the appointment of the same ministers (either simultaneously or in sequence) reveal blocks defined increasingly by religious ideology in the decades leading up to the Civil War. The blocks of religious patronage are the best predictors (better than an individual's own religious identity, ties to the court, or occupation) of affiliation and activism during the Civil War.

Bearman uses sociological techniques and a structural sensibility to produce a model which is far more predictive of the loyalties of Norfolk gentry in the Civil War than Marxist and revisionist historians who are unable to settle upon a method to join theoretical assertions with the muck of detail. Applied to all of England, Bearman's approach would go far in settling the seemingly intractable debates over the Civil War.

Bearman's book should be a tonic to sociologists as well. He reminds us of the value of our discipline. Our understanding of social structure allows us to "abstract from context to yield pattern." Those patterns in turn allow us to model identity and thereby impute "motive to actors on the basis of the position that they occupy in a network of positions." Bearman's methodological precision and theoretical clarity provide a model for sociologists and for historians.

Art Crime.
By John E. Conklin. Praeger, 1994. 322 pp. Cloth, $49.95.

Reviewer: KURT LANG, *University of Washington*

Almost overwhelming in its array of synopses of specific "art crimes," with biographies of perpetrators and victims, descriptions of techniques typical of art thieves and art forgers and of situations that tempt them, this book by John E. Conklin, professor of sociology at Tufts University and author of several previous criminology books, can be recommended for the fast-moving kaleidoscope it offers of just about everything you ever wanted to know about this diminishingly arcane subject. Yet, intriguing as these vignettes may be to the novice, anyone with some familiarity with the trade in art and antiques is unlikely to learn much from this book beyond some titillating details.

Data come mostly from news reports and from a handful of journals for collectors. Other material, particularly about the plunder and trade in antiquities, comes from *The Art Crisis* (1975), a mildly popular book by Bonnie Burnham. But Conklin's acknowledged reliance on such sources is not, for this reviewer, the major shortcoming of what, despite its well-paced movement from topic to topic, strikes me as scissors-and-paste sociology.

Not that *Art Crime* comes without the requisite "theoretical" introduction. It reviews some high spots in the literature on the social construction of value in art (also the subject of a separate chapter), on the motives underlying criminal behavior, on the neutralization stratagems by which such behavior is justified, and on the social organization of art crime. One only wishes that these subjects had been pursued more diligently and more systematically throughout a book that ends with a menu for curbing crime in this often speculative and potentially lucrative market.

It stands to reason, therefore, that many of the crimes most typical of the art trade — insurance fraud, bad checks, worthless collateral, violation of export restrictions, failure to acknowledge conflicts of interest — are also found in other areas of business. To be sure, Conklin is right on target in noting certain peculiarities of the art trade, among them tenuous nature of artistic value, the trust assumed in transactions, and the inexpertness of most purchasers. Nor is there any real parallel in the business world to art vandalism, to which he devotes a chapter. Nevertheless, in the opinion of this reviewer, who makes no claim to special expertise in criminology, the sociological relevance of this lively book could have been improved by some explicit references to the generic categories of fraud and theft into which these art crimes can fruitfully be placed.

More illuminating is the discussion of the mentalities of the perpetrators of art crimes. What I find lacking, on the other hand, is correspondingly detailed treatment of the legitimate artist as either an offender or victim. Creative individuals are often pushed into "criminality" by the censorship policies of repressive regimes. Faced with the export ban imposed on all but a few favored artists in the former Soviet bloc, many of them managed to smuggle their work out of the country. Almost every artist I interviewed last fall in what used to be the German Democratic Republic proudly told of some illegality by which he or she had outwitted the authorities. And, finally, while *Art Crime* tells us a good deal about the victimization of artists by gallery owners, it barely touches on the many infringements of artists' copyrights, about which they are forced forever to be on the defensive. Unfortunately such ordinary crimes rarely make journalistic headlines. This book, too, in its selection and treatment of examples seems to have been driven more by their newsworthiness than by their sociological relevance.

Inequality, Crime, and Social Control.
Edited by George S. Bridges and Martha A. Myers. Westview, 1994. 330 pp. Cloth, $59.95; paper, $33.95.

Reviewer: BARBARA J. COSTELLO, *Mississippi State University*

This work is a collection of sixteen essays developed from a 1992 University of Georgia conference. The essays are organized around four themes: (1) the extension or integration of social control theories, (2) the refinement of conceptualizations of inequality and its relationship to crime and social control, (3) the specification of the nature and direction of relationships among various forms of social control, and (4) analysis of the processes by which individual and group values come to be reflected in law and official reactions to deviance.

The major strength of this work lies in the diversity of new theoretical approaches it presents. Tittle's essay provides a compelling argument for theoretical integration by pointing out that four seemingly divergent perspectives (consensus, conflict, social psychological, and bureaucratic) all predict inequality in sanctioning, though each contains flaws precluding the complete explanation of this inequality. Liska argues for the refinement of conflict theory, which as currently formulated and tested "explains everything and predicts nothing." He bases this claim, in part, on the fact that conflict theory can explain apparently contradictory empirical findings. For example, increasing organization of minority groups can lead to an increasing threat to the majority and consequent increases in social control, but it can also lead to decreases in social control through the minority's increased ability to resist control. Liska also criticizes the disjointed nature of the literature on conflict theory, which is organized by form of social control rather than by theoretical propositions. Platt's analysis of recent developments in the field echoes many of Liska's concerns and calls for abandoning the case study approach in favor of a broader, multidisciplinary approach to social control issues. The final contribution in the general theory section is Peter Manning's innovative application of Bourdieu's structuralist theory to the policing of domestic violence.

This diversity continues throughout the remainder of the book, which contains additional theoretical developments as well as empirical analyses. Unfortunately, the diversity that is the strength of the work is also the book's major weakness, as the authors often ignore each other's conclusions and recommendations. For example, Kathleen Daly argues that studies of gender differences in sentencing, including her own prior work, have overlooked subtle differences between the seriousness of men's and women's offenses that can explain virtually all observed sentencing "disparity." In a subsequent chapter, Bridges and Beretta cite Daly's prior work as evidence that gender differences in crime cannot explain gender differences in imprisonment. They further argue that "explanations of disparities in punishment must move away from perspectives that rely heavily on differences between men and women in criminal behavior."

Tolnay and Beck's analysis of Southern black lynchings does not ignore earlier recommendations but seems to misunderstand them. They cite Tittle's argument for the integration of consensus and conflict perspectives, implying that his recommendations are valid, yet go on to state that "there can be little doubt that Southern whites shared a strong consensus that blacks were . . . a threat to the integrity of their cherished society." They therefore misinterpret consensus theory as implying that consensus exists only *within* conflicting interest groups, which is actually an assumption made by conflict theorists.

These contradictions would not be so troubling if they were presented as points of contention, but Bridges and Beretta do not argue against Daly's current perspec-

tive and Tolnay and Beck do not explicitly criticize Tittle's arguments. Granted, it is difficult to compile sixteen papers into a completely coherent volume, especially when the goal is to present innovations in a field. Nonetheless, I was left wondering who will be likely to follow the authors' recommendations if not their fellow contributors.

Crime in the Making: Pathways and Turning Points Through Life.
By Robert J. Sampson and John H. Laub. Harvard University Press, 1993. 309 pp. $32.50.

Reviewer: ROLAND CHILTON, *University of Massachusetts at Amherst*

This book reexamines delinquency and crime data collected by Sheldon and Eleanor Glueck from 1939 to 1961 and is a benchmark for current and future longitudinal studies of crime and delinquency. After recasting the data, they were able to reassess much of the criticism of the Gluecks' book, *Unraveling Juvenile Delinquency* (1950). More importantly, they use the data to illuminate and advance several current theoretical and empirical issues in criminology.

In the opening chapters, Sampson and Laub present (1) a theoretical framework, (2) the Gluecks' perspective, (3) a detailed description of the Gluecks' study, and (4) a description of the procedures used to reorganize the basic data. Their discussion of the work and the backgrounds of the Gluecks provides a convincing explanation for the limited impact of *Unraveling Juvenile Delinquency* on main stream criminology. Subsequent chapters reassess the importance of informal family control and school, peer, and sibling influences by looking at the probable contribution of structural factors, process variables, and propensity measures to official and unofficial delinquency. Their basic conclusion after these initial analyses is that "when the bonds linking a youth to a society — whether through the family or school — are weakened, the probability of delinquency is increased."

However, perhaps the most important results are found in the chapters focused on the continuity of behavior over time and the impact of social bonds on adult behavior. They find continuity in official criminal behavior over a thirty-year period but then explore the possibility that adult social bonds explain variations in adult crime beyond those explained by childhood differences. After exploring this possibility, they conclude that "childhood delinquency and adult social bonds (job stability and marital attachment) independently explain significant variations in adult crime."

The book has two additional components, a qualitative analysis of some of the voluminous files created by the Gluecks' research staff and transcripts of interviews with three of these staff members. There were several advantages to using data collected by the Gluecks, including the detail and the range of information sources, the availability of self-reported, parent-reported, and teacher-reported delinquency, and a very successful follow-up effort. However, a major limitation of *Crime in the Making* is the limitation produced by the Gluecks' original research design. It is a comparison of 500 young white males held in two Massachusetts prisons for juveniles with 500 nonincarcerated young white males who were living in poor communities in Boston in 1939. Most lived through a great depression and were followed through a great war and a postwar period. Sampson and Laub argue that this is a strength of the study because it provides an important comparative base for assessing current concerns of race, crime, and the underclass.

I think the data would have been more useful if it had *not* been limited to white males in poor neighborhoods. It would have been useful then, and would be today,

to know why so little crime is committed by girls and women. Moreover, the Gluecks truncated the social class distribution when they focused on poor neighborhoods and excluded black delinquents. As a result any conclusions about the impact of social class are weakened.

This limitation aside, the book is an important effort that will be of great value to criminologists and criminology students for years to come. This is primarily because of the authors' willingness to examine the impact of structural, interactional, and propensity factors in the production of delinquency and crime. *Crime in the Making* is an important and well-crafted explanation of why some children become delinquent, why some adults become criminal, and why only some of these children and adults continue to engage in criminal conduct as they mature.

Wannabe: Gangs in Suburbs and Schools.
By Daniel J. Monti. Blackwell, 1994. 174 pp. Cloth, $16.95.

Reviewer: MALCOLM KLEIN, *University of Southern California*

With the proliferation of gangs of many sorts across the country, there has emerged a matching proliferation of new research studies of gangs. With a few notable exceptions, these new studies are case studies either of a single gang or of a single city with gangs. Generalizable knowledge thus depends on the ability and willingness of case study authors to describe the parameters of these gangs or gang situations, and to relate these to what has been revealed in prior published work. *Wannabe,* a report on suburban gangs in a midwestern metropolitan area based on youth interviews in elementary, junior, and senior high schools, is deficient on both criteria for deriving generalizable knowledge. Although engagingly written and sprinkled with interesting quotes taken from the interviews, the work is of indeterminate value.

While he acknowledges the ambiguities inherent in defining or depicting gangs, Monti offers little by way of definitional clarity. Because his interviews are with unknown proportions of nongang and gang respondents, ranging from elementary to high school ages, the boundaries of "gangness" are hard to discern. The book's title belies the seriousness of involvement of a number of these respondents and other gang members they describe.

Research is limited to interviews in school, often with a counselor present. No corroboration of interview reports is attempted via official data, nor by street or other observation, nor by interviews with teachers, other officials, parents, or dropouts. Also, respondents were warned not to speak of their delinquent offenses (though some did). Thus we are offered no crime data, no demographics, no analysis of differences between gang members and nonmembers, little on gang histories or structures, etc. The problems are exacerbated by what, to this reviewer, seem to be rather intrusive and leading interview procedures.

Until the last chapter on policy issues, which cites but makes minimal use of prior research, there is virtually no scholarship in this work. Presumably this can in part be attributed to the attempt to reach a wide lay audience, but it also reflects Monti's view on prior research as "social scientific claptrap" and "drivel." In the final chapter he characterizes his fellow social scientists as "a sociologist, psychologist, or any other slick expert pushing an open hand and an empty head."

This disdain for and ignoring of prior works leads Monti to some serious errors. He claims to be the first to study gangs in suburbs; he says that independent female gangs are a new phenomenon; he seems surprised to find gang members coming from middle-class, two-parent families; he concludes that "gangs are democratic to

a fault," being equally open to all ethnicities, and equally open to middle- and lower-class youth; he concludes that where gangs are formed is unimportant, characterizing other work on this issue as existing only "in Frederic Thrasher's mind. All the researchers who faithfully followed the path he cut made the same mistake and were as lost as he was."

Failure to follow the literature on the relationship between street gangs and drug sales leads Monti to a series of confused and contradictory descriptions of this relationship, and of the place of migratory Bloods and Crips in spreading drug markets. Indeed, when his respondents offer contrasting views on drug issues and on the importance of big-city gangs in his suburbs, he is at a loss even to attempt any resolutions. Other scholars' reports and other methods could have helped him in such circumstances.

In sum, another opportunity to add to our general knowledge of gangs has been missed. If Monti had presented his materials in the spirit of exploration, this review could have been more positive. Instead, he presents his findings and conclusions as rather definitive knowledge about a heretofore undiscovered phenomenon. Since we are not provided with replicable methods or data, such knowledge would seem to be on shaky ground. This reviewer is not satisfied with "revealed truths."

Street Kids, Street Drugs, Street Crime: An Examination of Drug Use and Serious Delinquency in Miami.
By James A. Inciardi, Ruth Horowitz, and Anne E. Pottieger. Wadsworth, 1993. 234 pp.

Reviewer: HILARY SURRATT, *University of Miami School of Medicine*

This study provides a much needed account of the drug use and criminal involvement of a large cohort of seriously delinquent youths in the Miami, Florida, area. The authors' use of street research techniques provides empirical data on a hard-to-reach population that has been understudied by traditional delinquency research. The beginning of the book presents a comprehensive overview of traditional delinquency theories including social disorganization, control theory, and social learning theory, but asserts that none of these perspectives is sufficient to explain serious juvenile involvement in crime and drugs. While much media attention has been focused on young crack users since the mid-1980s, little empirical research has been conducted on adolescent criminality and drug use and therein lies the contribution of *Street Kids, Street Drugs, Street Crime.* The authors provide in-depth drug use and criminal histories for a multi-ethnic sample of 611 serious delinquents who exhibit a pattern of drug use from alcohol, to marijuana, to powder cocaine, and finally to crack-cocaine. The vast majority of these were found to be polydrug users who began using crack at the alarmingly early age of 14 years. Despite the magnitude of the adolescent drug problem, the authors point out that there remains a serious lack of drug treatment facilities for juveniles. Only 4% of this sample had ever been in a drug treatment program, which presents a strong argument for compulsory drug treatment of those coming to the attention of the criminal justice system.

These delinquents reported an astonishing number of criminal offenses in the previous twelve months. Drug business offenses, especially retail drug sales, were reported by almost every respondent and a staggering 88% of the female respondents had engaged in some form of prostitution. Importantly, while previous research has suggested that black males commit a disproportionate amount of serious juvenile crime, the findings of this study do not support such a conclusion. The authors found that the *overall* crime level does not vary significantly by either

gender or ethnicity, and they emphasize that crack use and crime are not just problems among inner-city, minority juveniles but among white working and middle-class young people as well.

In the closing chapter of the book, the authors present what is perhaps the most important public health implication of this research: the potential for HIV transmission. Although reported cases of AIDS among adolescents are infrequent, the introduction of crack-cocaine among adolescent drug users may be a contributing factor to infection with HIV. The use of crack has been associated with higher levels of sexual activity, through prostitution and barter of sex for crack. In addition, a significant number of the 611 young people interviewed in this study were engaging in behaviors that put them at risk for HIV infection.

Overall, this is an important book for both students and researchers in the areas of delinquency, criminology, and substance abuse, because of the contribution it makes to our knowledge of chronic criminal behavior and drug involvement among American youth.

Childerley: Nature and Morality in a Country Village.
By Michael Mayerfeld Bell. University of Chicago Press, 1994. xi + 279 pp. Cloth, $32.50.

Reviewer: GEORGE A. HILLERY JR., *Virginia Polytechnic Institute and State University*

This an excellent book. Well written and well organized, it is a pleasure to read. To a large extent, Bell lets the people tell their stories about things of interest to *them*, and this helps make them interesting to us.

Childerley is an exurban English village of 475 inhabitants, about two hours from London. Since it is composed heavily of those who have rejected the city (at least as a domicile) and the anonymity of mass society, we are surprised to learn that "few Childerleyans know more than a small fraction of the other residents in the village." Yet the village is a relatively coherent entity.

Bell explores three main aspects of this entity: social class, the attitudes of the villagers toward nature, and the interrelatedness of village traits. Class is given most attention. Though there are numerous status variations in wealth, traditional social class (nobility and commoner), and occupation, the villagers usually think in terms of two levels. When visiting, who uses the front door and who the back door? The importance of class, however, is declining, as suggested by the people's distaste for it.

Bell deals with ecology in its original meaning: the relation of organisms to their environment. This approach shows especially in his treatment of the geography of the countryside and the relation of the people to it. Today there may be in fact little difference between country and city, but regardless of the facts, "every village resident agrees that there is such a thing as the country, distinct from the city — and every village resident agrees that this distinction is important." Many have come to Childerley precisely because of their desire for country life.

An impressive feature of the book is the emphasis on interrelatedness of village traits. Bell takes several key phenomena and shows how they influence what goes on in Childerley. Class especially is tied in with most of village life. We are given, for example, a clearer picture of lower and upper class relationships by a description of class-based differences in attitudes toward the fox hunt.

Bell achieves something not often found in sociology — a treatment of society both from the point of view of individuals and from the perspective of the society

and its institutions. He does this by selecting for intensive interviews representatives from each class and gender. The result does much to bridge the micro-macro gap.

More explicit emphasis is placed on gender than on family, which is interesting since the family has been a mainstay of class. Although families are mentioned frequently, Bell apparently feels that family is not as important as it once was. To understand community behavior, gender may indeed become more significant as family and group interests give way to individualism. Nevertheless, according to the descriptions Bell gives, family still explains much important behavior and could have been used more explicitly as an explanatory variable.

The strength of a book is often found in its weaknesses. *Childerley* has few. Though not a structural-functionalist, Bell nevertheless assumes that everything is related to everything else. Indeed, he gives this idea fresh perspective by introducing the concept of "resonance." Taking as his model the change ringing of bells, he suggests that ideas resonate with each other just as bells do. The model will probably prove useful as long as one does not follow it too closely. Human groups are not put together like bells. Their bonding is primarily symbolic, which means that connections between people are essentially arbitrary and basically indeterminant.

But when considered from a broader perspective, criticisms offered here will not appreciably detract from this truly outstanding work.

The Quest for the Other: Ethnic Tourism in San Cristobal, Mexico.
By Pierre L. van den Berghe. University of Washington Press, 1994. xii + 169 pp. $24.95.

Reviewer: ERIK COHEN, *The Hebrew University of Jerusalem*

San Cristobal is the center of ethnic tourism in highland Chiapas — and according to the author, a rare example of successful, small-scale, environmentally friendly tourist development. It is a *ladino* town, surrounded by a low-class, peasant stratum of Indian micronations that are the alleged goal of the tourists' quest for the "Other." Alas, it is also at the center of the Zapatista Indian uprising, and was briefly occupied by the rebel army in early 1994, about the time this book went to press. The coincidence is somewhat ironic, particularly since the optimistic tone of the book (written by an anthropologist with decades of experience in the area, who approaches tourism from the perspective of ethnic relations theory) misses any indications of the coming storm, even though the rebellion seems to have been under preparation for as long as eight years.

The omission is hardly a failure of the author, however, who went to San Cristobal for a three-month period of fieldwork in 1990, explicitly to study tourism. But it is an indication of the depth of the gulf still separating the urban *ladino* society, among whom the author lived, from the secretive Indian communities in the countryside; it is also an indication of the difficulty any student of tourism experiences in penetrating the front which even unassuming natives present to tourists and other strangers, and behind which frustration, despair, and animosity are frequently concealed. The Indians are described as dignified, but not unfriendly; the pent-up tensions break through only in the report of one incident — the killing, some years ago, of a foreign tourist in an Indian village, after he had disregarded repeated warnings not to take photographs. The uprising did not necessarily start in the communities visited by tourists; but it would be interesting to know whether tourism played a role in triggering it off.

The book is essentially an anthropological survey rather than an in-depth community study. The author describes in detail the five principal components of tourism in San Cristobal: the tourist attractions and facilities, the mainly *ladino* inhabitants of the town, the "tourees," (i.e., the Indians), and the tourists themselves. He presents some statistical summaries of his interviews with the tourists, as well as 25 "vignettes," brief descriptions of individual visitors, in order to illustrate their diversity. The Indians, rather than the urban *ladinos*, are the goal of ethnic tourism. They are the Other. But the *ladinos* are the owners of the tourist facilities and act as middlemen between the tourists and the tourees, reaping the principal benefits of the tourist business. The Indians, at the bottom of the traditional ethnic hierarchy, benefit principally from the sale of handicrafts and from begging in towns, where most of the contacts between tourists and Indians take place; Indian communities in the countryside, except one or two which became sightseeing attractions, benefit little from tourism.

Considering that this is the first book-length study of tourism in a Mexican town, it makes informative, though not particularly exciting, reading. Neither is there any significant theoretical innovation: the author analyses his data in terms of MacCannell's, conception of "staged authenticity," but he seems somewhat ambivalent towards such staging: while he discusses it critically in the body of the text, in the conclusions he advises covert staging as a strategy to preserve the ambience of the town.

Van den Berghe finds that tourism has improved the *ladinos'* attitude toward the Indians and their appreciation of Indian culture; it appears to have had an ameliorating influence on the rigid hierarchical ethnic relations of the highlands. But the Indians' position in the hierarchy has not changed significantly; and they have remained the inscrutable Other not only for the tourist but apparently also for the author. Indeed, the concept of the Other remains opaque throughout the book. We learn little about the meaning of the Indians' "otherness" for the tourists, and the author does not attempt to penetrate it for himself; if he did, he would perhaps be able to discover the seeds of the revolt hiding behind the impassive face of the Indian "tourees."

After Ellis Island: Newcomers and Natives in the 1910 Census.
Edited by Susan Cotts Watkins. Russell Sage Foundation, 1994. xviii + 451 pp. $49.95

Reviewer: TERESA A. SULLIVAN, *The University of Texas at Austin*

The nation's census is an investment in infrastructure that is valuable not only for the immediate concerns of reapportionment, marketing, and planning, but also as an incomparable portrait of the country that can be revisited again and again. This volume shows how a census can pay dividends long after its completion. Using the Public Use Sample of the 1910 U.S. Census of Population, the demographers who wrote these chapters examine child mortality, ethnic fertility differences, household structure, residential segregation, schooling and industrial affiliation of workers at the end of the first decade of this century.

The Public Use Sample is a national random sample of the manuscript census. Larger than the comparable 1900 data base, it allows for a richer analysis of relatively small immigrant groups. Most of the data were previously unpublished. The Census asked women about the number of children they had ever borne and the number surviving, but the survival data were never before analyzed. A rather lengthy appendix provides considerable detail on the sample, and Susan Watkins's chapter provides background on the 1910 census.

The Thirteenth Census reflected the concerns then, as now, with immigration and its effects. Most of the chapters in this volume take advantage of the variables of country-of-origin and mother-tongue to examine differences between native-born and foreign-born, among generations, and among linguistic groups. Published tabulations of the era, by contrast, often reported the "foreign-born" as a group, effectively masking the differences that later chapters of this volume reveal.

One set of intriguing findings concerns the child mortality of various nationality groups. The foreign-born population had relatively high child mortality, compared with the native whites, probably due to immigrants' concentration in large cities. French-Canadian child mortality was extremely high, and Jewish child mortality was quite low, anomalous results that might arise from breast feeding practices, according to the chapter's authors, Samuel H. Preston, Douglas Ewbank, and Mark Hereward. Second-generation Americans had lower child mortality than immigrants, and wives who married in the U.S. lost fewer children to early death than women who had married abroad. Child mortality among black Americans was very high, with a mortality index that began at 0.61 higher than native whites. Even after controlling for other variables measurable in the census, the index remained elevated by 0.41, a fact that might be attributed to the very marginal economic position of blacks forty-five years after the end of the Civil War.

The contrast between black Americans and immigrants is an important part of the national portrait in 1910. Ann R. Miller, in a chapter on the industrial affiliation of immigrants, argues that the industrial transformation of the U.S. labor force was made possible by the flow of immigrant labor to the cities. Over 30% of foreign-born whites were employed in agriculture, compared with 15% of native-born whites and fewer than 7% of blacks. The continued settlement of the western states, by contrast, was disproportionately the work of native-born whites, for whom agriculture remained an important industry. Considerable specialization among the other groups was evident, perhaps because of chain migration. Central Europeans were overrepresented in mining, where over 13% of them were employed, and in manufacturing, where nearly 45% were employed. Irish and Italians were overrepresented in transportation, and Eastern Europeans were overrepresented in trade.

Not so theoretically focused as Stanley Lieberson's *A Piece of the Pie*, this volume is a signal contribution to the literature because of its rich new data base and sophisticated modeling. Given the renewed significance of immigration as this century ends, this scholarship has the added potential of shedding light on current controversies. Finally, this volume represents a cautionary tale for our current Congress. Congress did not restrict the Thirteenth Census to a seven-item short form; 85 years later, we are benefiting from the wisdom of that decision. What we will know about ourselves at the turn of the twenty-first century depends upon our willingness to make the same kind of investment in ourselves now.

The Post-War Generation and Establishment Religion: Cross-Cultural Perspectives. *Edited by Wade Clark Roof, Jackson W. Carroll, and David A. Roozen.* Westview Press, 1995. xx + 291 pp. $55.00.

Reviewer: KEVIN J. CHRISTIANO, *University of Notre Dame*

A great many words have been written in newspapers and magazines and carried over the airwaves during the last decade about an unexpected return to conventional religious practice by members of the generation born between 1946 and 1965, the so-called "baby boomers" who now dominate Western societies and in America account for one third of the total population. Having endured an adolescence of

material affluence combined with cultural unease, and after an early adulthood filled with history-making social turmoil, these scarred veterans of the sixties have quietly crossed the "generation gap," the story goes, and are ready finally for property-holding, parenthood, and some type of piety.

But is the journalistic impression accurate? To date there has been precious little sociological research on the topic of "baby-boomer" religiosity (the senior editor of this title has written one of the few extended analyses of the faith of American "boomers"). Moreover, almost none of the literature, to my knowledge, attempts to test generalizations anywhere outside the U.S. It is precisely this need that inspired the work under review.

Although assembled by a trio of well-known American sociologists of religion, this volume is actually the product of a long (and still too rare) transoceanic collaboration among members of the Société Internationale de Sociologie des Religions. In eleven chapters (plus opening and closing statements by the editors), the book brings together the work of fourteen researchers on fourteen countries, which the editors label "the most advanced contemporary nation-states, often described today as in a late- or post-modern phase." (For the record, they are England, Australia, the U.S., Denmark, Iceland, Finland, Norway, Sweden, Germany, the Netherlands, France, Belgium, Italy, and Greece.) What occurs with these cases, the editors maintain, "is suggestive of religion's fate in other modernizing places."

As wide as this selection is, the countries are treated in varying degrees of detail; Belgium, in fact, rates two different entries, while discussion of Iceland, Denmark, Norway, Sweden, and Finland is collapsed into a single chapter on "the Nordic countries." Indeed, many of these contributions, like Eileen Barker's elegant examination of the "gentle, secularizing pluralism" of British religion; or the lucid study of Roman Catholicism in France by Danièle Hervieu-Léger; or Liliane Voyé's too brief venture into the world of small Christian groups in Belgium, would be valuable for their descriptive content alone, even if they were trimmed of all theoretical musings. Nevertheless, some conceptual common ground does emerge.

Most of the authors conclude that, in one way or another, younger believers have rejected the moral absolutes that traditional religious authority imposes, and have reduced accordingly their involvement with the forms of religious activity that "establishments" have to offer. Instead, "boomers" of the modern West have opted in favor of a "new spirituality" that is voluntary, open, emotional, and decidedly subjective — if not wholly solipsistic. Like the collection's Italian contributor, Salvatore Abbruzzese, the majority of the writers find that "the true detachment of this generation is not from . . . religious beliefs but from the institutions representing them; it is not a decline of the sacred as much as a decline of the church's authority as a moral guide."

No matter how exceptional and therefore important, this compilation deserves to be followed by much more research with a rigorously cross-national approach. In the meantime, a moderately priced edition would allow these first fruits of comparative effort to circulate among a broader range of readers everywhere — including, and perhaps especially, students.

Judgment and Sensibility: Religion and Stratification.
By E. Digby Baltzell, Edited and with an introduction by Howard G. Schneiderman. Transaction, 1994. 313 pp. $32.95.

Reviewer: PHILLIP E. HAMMOND, *University of California, Santa Barbara*

No sociologist can claim more of Tocqueville's legacy than E. Digby Baltzell, especially when it comes to Tocqueville's fear of the consequences of democratic equality. Where the French commentator referred to broken links of a chain, each concerned only for itself, Baltzell has his own ways of putting the matter: "John Winthrop would have been horrified with the permissive paradise sought by the Me-people of the 1960s." "John F. Kennedy's entering class at Princeton in 1935 [he later transferred] . . . ranked below the national average in IQ . . . ; the entering class today is at the very top levels of the nation academically. . . . The school for gentlemen has been replaced by a school for preprofessional men and women." "A WASP establishment . . . is no longer possible or desirable today. Some sort of authoritative establishment, however, may be a prerequisite for the ordered freedom which we and the British have enjoyed to a greater extent than any other nation in modern times."

All can agree, then, that "judgment" belongs in this book's title, but many teeth will be set on edge by the "sensibility" part. It is not because Baltzell would restore privilege to a Protestant establishment. He clearly recognizes that, while it may have persisted a few decades longer in culturally pluralistic and tolerant Philadelphia than in Puritan Boston and elsewhere, Protestant monopoly of wealth, club membership, board membership on non-profits, political office, etc., were disappearing phenomena by the 1920s. (Robert Handy, in *A Christian America,* even pegged this period "the second disestablishment.")

Some, however, are bound to be upset by Baltzell's nostalgia — for genealogy, for the gentleman's code in sports, for deference, just to name a few. Those more infected by the counter-culture of the 1960s, or the multiculturalism of today, will be inclined only to rejoice in new-found freedoms; they will be less inclined to remember, for example, the craven responses to Joe McCarthy until the Brahmin Joseph Welch challenged him in Senate hearings with an authority based not just on law but also on "class" — or, if you will, on "fair play," "justice," or "tradition."

All such ideas are easy targets in this so-called postmodern period, perhaps inevitably, given the ease in past decades with which able-bodied, Protestant, heterosexual, wealthy, white males had assumed positions of authority without seriously questioning their right to that authority. But this is not what Baltzell is questioning — what he is questioning is the consequence of overthrowing an American "ancient regime" without attention to its replacement. As he puts it, "Until intellectual leaders . . . come to see . . . that freedom of intellect and liberal democracy are only possible in deferential and hierarchical societies, our forever bickering society will degenerate into the anarchy or tyranny that has marked so much of the third and Marxist worlds."

The various chapters of this collection, dating from 1954 but most more recent, provide ample display of Baltzell's views of this serious issue. The fact that he has no solution — to restoring a "civil religion," for example, or renewing a vibrant and uniform "public opinion," or redefining "self-interest rightly understood" — does not negate his perceptive observation on the collapse of the noblesse oblige ethic that was once part of the American elite class.

Having said all that, however, I must register a negative report as well. The book is 313 pages, of which 6 are an index, 23 are a well-crafted introduction by the editor, Baltzell's admiring former graduate student, 130 are articles or essays of

substance (of which about half are original in this volume), and the remaining 154 are reprinted book reviews, newspaper comments, editorials, etc. In other words, half the book is made up of Baltzell's often trenchant, but brief, observations on the passing scene. There is little, therefore, in the way of sustained argument. Because Baltzell is a graceful and witty writer, this situation is not all bad, of course, but it does make for a book with limited appeal.

Status and Sacredness: A General Theory of Status Relations and an Analysis of Indian Culture.
By Murray Milner Jr. Oxford University Press, 1994. 336 pp. Cloth, $60.00; paper, $24.95

Reviewer: BAM DEV SHARDA, *University of Utah*

The Indian caste system has been the subject of analysis by numerous scholars. The dominant theme in these writings has been to illustrate the unique features of the caste system. Best known among the contemporary western writers on this subject are the French structuralist Louis Dumont, and the American Indologists McKim Marriott and Ronald Inden. They argue that the traditional categories in India are *varnas* or caste clusters ranked by level of purity and should be understood "Indic categories" alone. They, and many other writers (with few exceptions), therefore, argue that the Indian caste system is not directly comparable with other systems of stratification.

In his book, *Status and Sacredness,* Murray Milner, Jr. argues against this and other "orientalist" positions. He has undertaken an extensive analysis of India and argues for a comparative approach. He builds a general theory of status relations from the Indian data, but argues that this theory should be applicable to all societies. For this purpose, he incorporates Weberian theory of status groups with the Durkheimian notions of sacredness. This analysis, he argues, could also offer useful insights into the transition of the modern/developed industrial societies to their postmodern/postindustrial phase.

Many great civilizations (e.g., the Greeks and Romans) made remarkable strides but are extinct now. We only read about them in the history books. Indian civilization, on the other hand, has thrived throughout the ages, despite numerous attacks from outside and within. Why? This resilience of the Indian civilization lies, argues Milner, in the Brahmins' genius for making status the key resource rather than wealth or political power. Convertibility of wealth and power and the problems of legitimacy made the elite in other civilizations the object of discord and hence was a major reason for their downfall. Brahmins in India, on the other hand, used the elements of sacredness to insulate the status resource from the profane world. The profane or material resources were allocated to the other twice-born *varnas*/ caste clusters, whose duty it was to protect and provide for the Brahmin elite. Thus the source of their legitimacy remained in their status.

In describing the social categories in traditional India, Milner argues that *ritual status* was and is the core of Brahmin identity and power. Purity of food and association and sexual asceticism remain their major concerns. However, the economic and political elite (the *Vaishyas* and *Kshatryas)* are more concerned with auspiciousness and the removal of inauspiciousness, which only ritually pure people with special knowledge of astrology can do. Thus, status is the only source of legitimation in India. In an ingenious way, Milner shows how the missing categories of renouncers, untouchables, and bandits become part of the system and how the

status of *Vaisya varnas*/castes, though a part of the traditional social categories, remain ambiguous.

To support his arguments, Milner reviews evidence concerning the continuous cultural prominence of Brahmins, the careful restriction of (status) mobility, the centrality of the concept of *dharma* in daily life, the regulation of eating and marriage arrangements, and the pervasiveness of ritual gift giving. Status (nonmaterial sacred resource), argues Milner, is inalienable, and inexpansible and hence a much more stable resource than wealth or power (the material resources).

Status is a zero-sum resource. If some caste group gains status then the others (higher ones) must lose. In order to limit the transfer of status, ritual norms are prescribed for the higher (privileged) castes, which are protected by elaborately coded "secondary norms." Only members of the privileged strata can learn to "decode" these norms, which include useful rules for enacting associations (e.g., marriages). Thus, the rules of commonsuality and endogamy are devised with care to protect the privileges of higher castes and their identities.

It is understandable that the twice-born castes claim higher status but why should the untouchables, the *shudras* (lower castes), or even the poor Brahmins accept their low nonmaterial or material status? Milner's answer is in his formulations of the Hindu concepts of soteriologies (the means to liberation) and eschatology (about the other worlds) which are conceived as structural reversals of this world. Specifically he argues that: (1) whereas there is inalienability of social status in this world and hence no mobility, *samsara* (literally flow/flux) is a form of social mobility through re-incarnation or transformation; (2) whereas purity and pollution differentiate castes in this world, *moksha* (liberation) becomes the goal of all human beings irrespective of caste; and (3) whereas ascription and inheritance is the key to status in this life, individual *karma* or merit (within the framework of one's *dharma*) is the only way to advance toward liberation. These formulations are the most original and convincing that I have seen in the literature.

I have one small correction and a criticism. On page 16 (last paragraph), the number of *puranas* should be eighteen and not sixteen as reported, perhaps a printing error. My criticism is of Milner's analysis of status. He rightly points out that the most important development in sociology in the last quarter century has been the recognition of non-material resources, first in the notion of human capital (education and skills) and more recently in the notion of symbolic capital (variously referred to as social capital, cultural capital, etc.) in the work of Bourdieu and others. However, both of these notions, Milner believes, ultimately reduce nonmaterial resources to material resources.

Milner's analysis is unique in considering "sacredness [as] a form of status." In the discussion, however, status is reduced to notions of sacredness. This is not at all warranted. In the caste hierarchy Brahmins are universally ranked at the top, but in occupational prestige rankings their traditional occupation (i.e., priest) is not placed that high. This indicates to me that status has two dimensions: ritual status of caste members and secular status provided by their occupational roles. Both can be nonmaterial in nature. The first one is ascribed and inherited whereas the second one may be either achieved or inherited. Thus this one limitation of the book may be noted along with its great importance to the literature.

I believe Milner's book will become very influential in the debate between comparativists and Indologists. However, this time around the Indologists, whether of orientalist or imperialist orientation, will be shooting at a real target rather than at a straw man as they have been doing for so long. In my opinion, Milner has outlined a framework for a genuine synthesis of sociology of religion and stratification that has been neglected in the literature so far. This book is a must for South

Asianists and students of comparative stratification. It will also be useful in graduate theory courses in sociology.

Playing by the Rules.
By John Wilson. Wayne State University Press, 1994. 429 pp. $39.95

Reviewer: ARTHUR T. JOHNSON, *University of Maryland Baltimore County*

Playing by the Rules is a wide-ranging effort to explain the relation between state and society as it affects sport or, more specifically, "the process whereby sport has become a public policy domain." Its guiding thesis is that "policy domains are defined primarily by culture." The recurring theme is to explain sport policy outcomes in terms of "the contradictory forces under which the state must operate in capitalist democracies."

Wilson conceptualizes sport and organizes his chapters in terms of individual, organizational, institutional, and societal levels. He argues that the politics of sport marginalize certain groups and limit the liberty of athletes to exploit their talents. Wilson contends that in the U.S. liberty has been emphasized over equality, resulting in unequal access to leisure opportunity as evidenced by the exclusion of African Americans from professional sports and women from sport in general. At the organizational level, the debate is whether sport organizations should be treated as private or public entities. State action shapes modern sport business and harnesses national values to economic goals in order to ensure viable sport enterprises. At the institutional level, public debate centers on the role of sport in the community and the role government should play in ensuring public access to sport. At the societal level, the state uses sport to promote political assimilation and to symbolize national identity, especially in international competition.

The book's chapters treat barriers to participation, athletic eligibility, anti-trust issues, labor relations, governance of sports leagues and associations, franchise location and movement, mass media, state provision of parks, recreation spaces and athletic facilities, political mobilization and integration, and the role of the U.S. in the international sporting order. Each chapter is primarily a descriptive discussion, based mostly on secondary sources from before 1991 and Congressional committee reports and hearings. Discussion of court cases appears to rely on others' analyses rather than the author's.

As comprehensive as this book attempts to be, it fails to address the one area that would appear to offer the most fruitful examination of Wilson's theoretical claims — that of tax policy toward sports organizations. If, as Wilson claims, sport businessmen have been successful in creating "a state policy toward sport that better protects their investment," tax policy would be a valuable source of evidence to test this thesis. Not one reference is made to taxes, however.

Minor flaws undermine the reader's faith in the author's treatment of his material. The overgeneralizations and trivial errors of fact cause consternation. For example, he says that the modern professional athlete is more likely to be black (in baseball, tennis, golf, hockey, auto and horse racing?); the public has been slow to acknowledge that sports is just a business (perhaps in the 1960s and 1970s, but in the 1980s and 1990s?); and sports and the mass media cannot exist without each other. The claim that NFL owner Robert Irsay accepted the highest bid when he relocated the NFL Colts from Baltimore to Indianapolis is not accurate (Baltimore's bid was actually higher). Ronald Reagan did not portray Knute Rockne in the film, *Knute Rockne — All American* (Pat O'Brien did). Northeastern University is not a public institution.

In sum, this is an overly ambitious text which suffers accordingly. Factual errors, poor copyediting (pages 222 and 223 are misplaced), confused time periods, important omissions, overgeneralization, and at times superficial treatment of the facts detract from the author's analysis. His failure in the concluding chapter to connect the historical description to his early theoretical introduction weakens the book's potential value as a needed source to provide meaning to how sport, the state, and society are related in the U.S.

Engineering Culture: Control and Commitment in a High-Tech Corporation.
By Gideon Kunda. Temple University Press. 1992. 297 pp. Cloth, $34.95.

Reviewer: NANCY DITOMASO, *Rutgers University*

This is a fascinating book for several reasons. It is beautifully written. It is a model of what a book on organizational culture should be (and it recently won the prize for the best book in the Culture Section of the American Sociological Association). It focuses on process and provides the feel of the organization, or in Evelyn Keller's words, the "feeling for the organism." But it is also an anachronism. It is a description of a "super" company that only a few years ago was a model for everyone else, but which has more recently fallen out of favor with almost everyone, for both strategic and technological missteps, and therefore, for also mishandling its own culture. In a recent rating of noteworthy corporations, it was rated last in its industry. Further, this book and this company both appeal to images of corporate culture at a time when such a concept has little currency in the new management fads and fashions. Now the talk is of "jobless" and "boundaryless" firms, and the end of the psychological contract. Loyalty is no longer exchanged for job security. Instead, managers are now encouraging employees to think of themselves as "Me, Inc." (i.e., as temporary employees who should keep their eyes on their own careers), rather than expecting the company to be concerned about such matters. Loyalty and commitment, the essence of the culture metaphor, therefore, are impediments in the paradigm of the "new" organization.

Kunda's purpose is to show through an ethnographic portrayal of everyday experience how culture is "engineered." As he says, he tries to examine the "practical, scientifically informed, self-conscious attempts to design and manage culture," offering an ethnography of "lay ethnographers" in a company whose leaders are committed to the utility of culture as a way to run the business. In this regard, Kunda poses two alternative views of engineered culture, collective "highs" or a new, more personal form of management control. Kunda organizes the description of the company culture around three main ideas: ideology, presentation rituals, and the self and organization. He provides some detail about how the images of the company are produced and made available to employees, the practices by which the culture is made meaningful, and the forms of experience that lead organizational members to define themselves and others in the company. Throughout he contrasts the way the culture enhances self-expression and commitment while also sucking up, burning out, and sometimes keeping out those in the organization's midst.

This book should be read at several levels. It provides a well-crafted ethnographic study of everyday life in a large organization during a time of its strength, and shows how the pressures for solving the conflict between individual and organizational goals affect both the way the organization manages itself and the responses of organizational members. It also, by both its contents and themes, provides a cautionary note for academics who would like to make a difference. The

research for this book was done about a decade ago, and its appearance now is a commentary on how long it takes to do truly good work. But, it appears just as the management winds have shifted, from the frenzy about corporate culture to the equally evangelical fervor about de-bureaucratization, boundaryless and jobless firms, and networks of dense relationships with no center. Perhaps the warnings about the "dark side" of culture have led corporate leaders to abandon it as well, but not because of the "symbolic violence" it engenders. Instead, companies seem to have abandoned the attempt to engineer culture, because of the potential costs of having employees so personally involved and expectant about the company's future. Thus, we can, like Kunda, pose a new dilemma. Is the lack of control and commitment a new form of tyranny or, for some, a new form of freedom and opportunity?

Response to Disaster: Fact Versus Fiction and Its Perpetuation, The Sociology of Disaster.
By Henry W. Fischer, III. University of America, 1994. 160 pp. Cloth, $46.50; paper, $18.50.

Reviewer: RUSSELL R. DYNES, *University of Delaware*

Fischer's short book focuses on a restudy of certain findings from early disaster research, which was unsystematic. Fischer is particularly interested in disaster mythology.

In the early 1950s, the first social science disaster researchers concluded that human beings do not behave in commonly expected ways during disasters: they do not flee in panic, they are not rendered passive, nor do they engage in antisocial behavior. This evidence, however, seems to have had little effect on the beliefs of emergency managers, community officials, and ordinary citizens. These beliefs have come to be called "disaster myths."

Fischer, in a short introductory chapter, provides an initial conceptual discussion as well as a short history of the research field. He then reviews the discrepancy between disaster mythology and research on disaster response, and studies the role of the mass media in perpetuating this mythology, using forty years' worth of disaster stories from a national news magazine. Lastly, he offers an intensive case study of the media coverage of Hurricane Gilbert in 1988 in which he suggests that local TV coverage sought to present information helpful to the community while network TV wanted a "good" story, which meant using more mythology.

Fischer also looks at the issue of developing an effective organizational response to disaster impact, focusing first on the role and training of local emergency managers. He finds that they are more accurately informed about disaster myths than a similar group twenty years before, which underscores the importance of education and training. He then looks at the impact of the media on local emergency operation centers. This case study indicates that a relatively small amount of press criticism evoked significant modification in the behavior of local emergency managers. Finally, Fischer examines the role of experience on the part of the local emergency manager in the creation of mitigation planning.

In his effort to replicate and cumulate such research evidence, Fischer uses surveys, participant observation, field interviews, and content analysis. In addition, he has used aggregate analysis combined with intensive case studies which often illustrate his findings more effectively and dramatically. While the book does not open any new areas of investigation, it strengthens the foundation on which current disaster research rests and that is useful.

Speaking of Life: Horizons of Meaning for Nursing Home Residents.
By Jaber F. Gubrium. Aldine de Gruyter, 1993. 197 pp. Cloth, $43.95; Paper, $22.95.

Reviewer: GEORGE L. MADDOX, *Duke University*

In a notably provocative foreword, David Maines proposes this slim volume as a partial antidote to what he perceives to be a weariness pervading sociology. This weariness is attributed to formula sociology (do a survey, run some statistics, test a model). In this process human agency is neglected and constructed persons replace people. Sociologists study interconnected variables, not persons in contexts. A contemporary student of sociology in an era of secondary analysis of large scale data sets may never meet any subjects face to face or observe personally what people do in various organizational or social contexts. Sociology remains the only academic behavioral and social discipline that has no acknowledged complementary applied component. These are now old complaints among sociology graduate students and some faculty whose hopes that social psychology or a phenomenological perspective would keep people in sociological analysis or bring them back to a more prominent place have not been fulfilled.

Gubrium proposes to do "nursing home ethnography," to give a face to go with a name, to explore the meaning residents perceive in their existence, and to find the possible connections and patterns between the meaning and their earlier lives. In this exploration he studies the narrative accounts of selected residents of nursing homes in response to an invitation to tell their story, to write their autobiographies chapter by chapter. This book, Gubrium writes, takes the "nursing home resident's life narrative as a point of departure for uncovering the subjective meaning of the nursing home experience in relation to the life as a whole." In such accounts one listens for themes and connections of the storyteller's own choosing. Gubrium uses the construct "horizons of meaning" to identify "patterns of narrative linkages each (person) makes with experience in and out of the nursing home."

Fifty-eight residents in several Florida nursing homes were interviewed, 33 of whom had been in residence over a year, a few for more than five years. Twenty-five residents were interviewed multiple times. No detail is given regarding issues of representativeness, reliability or validity of observations, or a theoretical framework for hypothesis or conclusions.

What the reader gets is what Gubrium promised: Very readable edited autobiographical narratives are organized under ten "orientations" such as "worried to death," "making a new home," "spouses" and so on. These observations are not theoretically derived; they are just observed to be there. Hence there is no report of the reliability or validity of the assignment. A relevant contrast in using social biography to predict "successful aging" is Williams and Wirths' *Lives Through the Years* (1965)

In a final chapter, the author does propose some lessons. One is that the lumping together of institutionalized older adults simply as "nursing home residents" is unjustified. Although no developmental theory is apparent in this volume beyond the expectation of lifecourse continuities revealed in the narratives, the storytellers are clearly role makers and role negotiators, not simply role takers. The insights and the sense of self and of efficacy occasionally revealed in some of the stories are notable. In fact, the cognitive intactness of the story tellers is also notable, reminding the reader that the probability of finding such cognitively intact older residents in a nursing home (average age 84) is perhaps in the range of one in two.

The methodological lessons Gubrium proposes involve the importance of giving the cognitively intact respondents free range to tell their stories, to ramble across

their narrative horizons. But the encounters were not freeform. An appendix sketches out an interviewer's guide for the life narrative project. Seeing the residents face to face, up close and personal is perhaps the only way, in the final analysis, to address the currently important issue of assessing the quality of life in long term care settings — which is not, Gubrium argues, equivalent to certifying the technological adequacy of care provided.

The book makes no attempt to estimate at the total quality of life of the residents interviewed and does not systematically characterize the facilities in which these residents live. Gubrium self-consciously avoids formal theory and settles for minimum interpretation and conclusions. The volume is "nursing home ethnography" and fulfills the promise of excellent narrative accounts of the lives of selected residents. Gubrium's next ethnographic account of nursing homes might usefully focus on the life stories of the providers of care, particularly the aides who spend their days interacting with residents.

Painful Inheritance: Health and the New Generation of Fatherless Families.
By Ronald J. Angel and Jacqueline L. Angel. University of Wisconsin Press, 1993. 264 pp. Cloth, $52.00; paper, $19.95.

Reviewer: DULA J. ESPINOSA, *Arizona State University*

Painful Inheritance is groundbreaking because it is one of the first comprehensive examinations of "the impact of minority group status, gender, and poverty on the physical and mental health of children and adult women in fatherless families." The book, which is carefully constructed and thoughtfully presented, reviews and critically analyzes measures of physical, emotional, and social aspects of health like infant mortality and immunization among children and stress and depression among mothers. The book also includes information on Hispanic families (a welcome departure from the more typical black-white only comparisons) and an examination of the effects of childcare on the health of older mostly Hispanic and Black women who are increasingly being called upon to care for their grandchildren.

Chapters 2 and 3 are particularly strong. The magnitude of the problem of "fatherless families" is clearly addressed in chapter 2, which documents the rise of single motherhood among blacks, Hispanics, and whites since 1960. While divorce is a major factor, the number of single teenage mothers is also increasing. The low education and low skills of many of these young mothers inevitably condemn them and their children to a life with little opportunity for social advancement.

The link between national policy and the health of people in single female-headed families is discussed in chapter 3. For example, a table shows how the U.S. differs from other industrialized nations in the types of universal entitlement support it provides to its citizen-families: Great Britain, Norway, France, West Germany, and Sweden, for example, provide family allowance, child allowance, housing allowance, health services, and parental leave. Speculating on possible effects of reductions in social service spending in the U.S., the authors cite the increase in infant mortality that began after cuts in prenatal care in the mid-1980s.

In later chapters, the authors review previous research and present new findings from their own research to show that single mothers generally do "have poorer physical as well as mental health than do married mothers," probably because they are more likely to be poor. This research also shows that black and Hispanic mothers are at an even greater risk for serious health problems than single white mothers.

In sum, *Painful Inheritance* shows that women and children in female-headed families are at a greater health risk than their counterparts in married families. Although the questions raised and answered by this work are important, more research will clarify the links between family structure and health risks. Among the most important of these questions are the health risks of children in "motherless" families, the health risks of children in two-parent families where one parent is abusive, and the potentially offsetting effects of a positive strong male (female) presence in a fatherless (motherless) family. Perhaps the most important question raised by this book is why people in the U.S. are so willing to allow poor women and children to suffer needlessly in order to maintain a relatively low tax base.

Femininities, Masculinities, Sexualities: Freud and Beyond.
By Nancy J. Chodorow. University Press of Kentucky, 1994. 132 pp. Cloth, $20.00; paper, $9.95.

Reviewer: CHRISTINE L. WILLIAMS, *University of Texas at Austin*

Psychoanalytic theory is routinely vilified by sociologists, including many who study gender and sexuality. Uppermost among their reasons for rejecting the theory is the presumed universality of its claims: After all, didn't Freud maintain that every boy experiences castration anxiety and every girl suffers from penis envy? Chodorow offers a compelling response to this criticism in *Femininities, Masculinities, Sexualities.* This book, a collection of three essays originally delivered as lectures at the University of Kentucky, reexamines psychoanalytic theories of gender, sexuality, and love. While Chodorow acknowledges that there are universalizing and normative strands throughout psychoanalytic writings on these topics, she argues that a significant undercurrent of diversity and difference is also present, particularly in the clinical case studies. In fact, her own direct involvement in clinical practice has led Chodorow to abandon most generalizations (psychoanalytic or otherwise) about "men," "women," "heterosexuals," and "homosexuals." These essays convincingly argue that the methods and insights of psychoanalytic theory can remain relevant in our postmodern age of indeterminacy and individual difference.

In the first essay, "Rethinking Freud on Women," Chodorow demonstrates that Freud did not have one all-purpose view of women. Freud's accounts of his women patients and his dealings with women psychoanalysts reveal remarkable tolerance and understanding of a wide range of feminine possibilities. Oddly, the subtlety and variation of these accounts are missing from his grand theory of "normal femininity." Why the difference? Chodorow contends that the femininity described in Freud's theory of female development can best be understood as "what femininity and women mean in the masculine psyche" — in other words, the theory of penis envy is a man's view of what a woman ought to be. As such, it tells us little about women's actual psychical development, but quite a lot about some men's (Freud's?) fantasies and conflicts regarding women.

The second essay, "Heterosexuality as a Compromise Formation," examines the problems with the psychoanalytic account of "object choice" (what most people call sexual orientation). Because Freud considered heterosexuality a natural and inevitable outcome of "normal" gender identity development, he spent little effort explaining how heterosexuality develops from the original bisexuality of infants. In contrast, Freud and his latter-day followers have developed a rich and nuanced account of homosexuality and the so-called perversions. In this essay, Chodorow makes a strong case that there are no clinical or theoretical reasons for treating heterosexuality and homosexuality as dichotomies: she writes that "the sexual

stories, conscious and unconscious fantasies, and transference processes of heterosexuals are as complex and individualized as those of homosexuals."

While Chodorow clearly rejects the privileging of heterosexuality in psychoanalytic theory, she also refuses to consider homosexuality a superior object choice. She suspects that there are probably objective indicators of healthy sexuality, but they have little to do with sexual orientation, *per se*. Thus, instead of trying to figure out how gays and lesbians differ psychologically from straights, Chodorow urges psychoanalytic researchers to develop new ways of distinguishing neurotic symptoms and disorders from passionate and healthy adult sexuality.

The final essay, "Individuality and Difference in How Women and Men Love," argues explicitly against universalistic theories of gender differences. Swimming against the tide of books which maintain some version of the Women-are-from-Venus-and-Men-are-from-Mars theme, Chodorow claims that "men and women love in as many ways as there are men and women." In any individual case, she maintains, gender influences the dynamics of emotional attachment in unique and particular ways.

Throughout these essays, it is apparent that Chodorow's growing familiarity with clinical case studies has shifted her own theoretical focus away from the universal claims about gender and sexuality implicit in Freud (and in some of Chodorow's own earlier work), toward a focus on individuality and diversity. For feminist sociologists, this new synthesis of psychoanalytic theory and postmodernist concerns arrives not a moment too soon.

Take Note

Bailey, Kenneth D. TYPOLOGIES AND TAXONOMIES: AN INTRODUCTION TO CLASSIFICATION TECHNIQUES. *Sage, 1994. 96 pp. Paper, $9.50.* This treatment of classification techniques concentrates on ordering cases in terms of their similarity. Two approaches are discussed — typology and taxonomy. A typology emphasizes the conceptualization of distinct dimensions along which the subject of interest varies. A taxonomy classifies cases empirically using their measured similarity on observed variables. After an overview of each technique the link between the two is explored.

Baxter, Vern K. LABOR AND POLITICS IN THE U.S. POSTAL SERVICE. *Plenum, 1994. 273 pp. Cloth, $39.50.* What were the antecedents and consequences of the reorganization of the U.S. Postal Service. This in-depth study of the country's largest civilian employer addresses the important theoretical questions related to employment, industry restructuring, technology and the political process of change.

Davis, Arthur K. FAREWELL TO EARTH, VOLUME II. *Adamant, Vermont: Adamant Press, 1993. 800 pp. $60.00.* Questioning assumptions about social change and social process, this collection of writings meanders through subjects as diverse as eugenics, industrialization, and mountaineering. A significant portion of the work is dedicated to essays on Thorstein Veblen and a section called "To the Socialist Nation." The latter reviews visits to China, Cuba, and the former USSR.

Jenkins, Philip. USING MURDER: THE SOCIAL CONSTRUCTION OF SERIAL HOMICIDE. *Aldine de Gruyter, 1994, 262 pp. Cloth, $41.95; paper, $20.95.* Jenkins explores the issue of serial murder and its construction into a social problem beginning in the late 1970s. The author examines the social and political climate that has surrounded this topic and how they have shaped the perspectives about serial homicide. He also looks at the role the mass media has played in creating the public sentiment of serial murder as a social problem.

Lee, Raymond M. DOING RESEARCH ON SENSITIVE TOPICS. *Sage, 1993. 248 pp. Paper, $18.95.* In an attempt to guide those engaged in research in sensitive areas, the author explores the potential impact of sensitivity at various stages in the research process — including formulation of the research question, design and implementation of the study, and dissemination of the findings. Additionally, the impact of ethical, political, and legal contexts for research practice is examined.

Prichard, Keith W. and R. McLaren Sawyer (eds.). HANDBOOK OF COLLEGE TEACHING: THEORY AND APPLICATIONS. *Greenwood, 1994. 488 pp. Cloth, $75.00.* An edited collection of works examining the issues confronting university and college professors in the classroom today. Drawing upon the knowledge of teaching faculty, educational specialists and theoreticians, the authors have constructed a handbook that addresses the psychology of learning, different teaching methodologies and theories, and common problems encountered in an undergraduate classroom.

Reed, John Shelton. KICKING BACK: FURTHER DISPATCHES FROM THE SOUTH. *University of Missouri Press, 1995. 180 pp. Cloth, $22.50.* Another humorous and perceptive collection of essays on various aspects of the American South by one of the foremost observers of the Southern scene. Topics that are explored include: state mottoes and mascots; stock car races; a Civil War reenactment; and politicians.

Rubery, Jill and Frank Wilkinson (eds.). EMPLOYER STRATEGY AND THE LABOUR MARKET. *Oxford University Press, 1994. 385 pp. Cloth, $65.00.* The role of employers in determining the quantity and quality of employment has taken on new importance in view of the rapid pace of industrial restructuring and the emergence of new employment policies. Drawing on new data from the Social Change and Economic Life initiative, this book examines how employers' policies impact employment structures and individuals' employment opportunities.

Taylor, Avril. WOMEN DRUG USERS: AN ETHNOGRAPHY OF A FEMALE INJECTING COMMUNITY. *Oxford University Press, 1993. 182 pp. Cloth, $35.00.* Ethnographical account of the lives and experiences of female drug users in Glasgow, Scotland. Taylor explores diverse issues such as how and why these women became drug users, with whom these women socialize, how they support their drug use, and their perceptions of the treatment options available to them.

Zelinsky, Wilbur. EXPLORING THE BELOVED COUNTRY: GEOGRAPHICAL FORAYS INTO AMERICAN SOCIETY AND CULTURE. *University of Iowa Press, 1994. 603 pp. Cloth, $49.95; paper, $22.95.* A marvelous collection of previously published articles by one of our most prolific and inventive cultural geographers treats everything from the spread of classical place names in the 19th century to the geography of Heaven, as revealed in cemetery names. Thought-provoking reading for anyone with the slightest curiosity about American culture and society.

Errata

In Kilbourne, England, and Beron's article "Effects of Individual, Occupational, and Industrial Characteristics on Earnings: Intersections of Race and Gender," published in the June 1994 issue (72:4), Tables 2 and 4 contain some incorrect data. The correct versions of the tables have been reprinted on the following two pages. Readers should note that while substantive conclusions made in the article remain largely unchanged, changes in the tables necessitate some changes in text where specific numbers are mentioned. For a corrected version of the entire article, please contact *Social Forces* at CB #3355, University of North Carolina, Chapel Hill, NC 27599.

TABLE 2: Decomposition of the Gender Gap in Pay, for Whites and Blacks[a]

	Male Mean	Female Mean	Percent Gap Explained Using: Male Slopes	Female Slopes	Weighted Average of Male and Female Slopes
Whites					
Experience (weeks)	342.01	265.07	38.5	29.6	35.1
Education (years)	12.92	12.80	2.6	3.3	2.9
Marital status	.64	.55	2.0	0	1.2
Percent female in occupation	19.52	79.60	3.0	10.0	5.6
Nurturant skill in occupation	-.02	.36	2.4	4.0	3.0
Cognitive skill in occupation	.15	.07	.2	1.1	.4
Industry position	.49	.66	2.6	0	1.6
Blacks					
Experience (weeks)	288.16	255.81	33.5	23.9	29.9
Education (years)	11.14	11.98	-34.6	-43.7	-38.0
Marital status	.47	.42	1.7	.5	1.3
Percent female in occupation	23.70	76.60	5.2	41.7	19.1
Nurturant skill in occupation	-.23	.07	2.5	2.0	2.3
Cognitive skill in occupation	-.70	-.47	-3.3	-1.8	-2.7
Industry position	.50	.63	4.7	.3	3.0

[a] Decomposition assesses percent of the natural log of hourly earnings gap between men and women explained by sex differences in means on each variable. Slopes used are those in Table 1.

TABLE 4: Decomposition of Race Gap in Pay, for Men and Women[a]

	White Mean	Black Mean	Percent Gap Explained Using: White Slopes	Black Slopes	Weighted Average of White and Black Slopes
Women					
Experience (weeks)	265.07	255.81	16.8	16.8	16.8
Education (years)	12.80	11.98	107.0	104.7	106.5
Marital status (married = 1)	.55	.42	.1	3.0	.7
Percent female in occupation	70.96	70.66	-0.2	-0.7	-0.3
Nurturant skill in occupation	0.36	0.07	-14.5	-4.7	-12.3
Cognitive skill in occupation	0.07	-0.47	33.7	10.1	28.3
Industry position (periphery = 1)	0.66	0.63	.1	.1	0
Men					
Experience (weeks)	342.01	288.13	38.9	41.9	39.6
Education (years)	12.92	11.14	56.3	54.9	56.0
Marital status (married = 1)	0.64	0.47	5.4	4.4	5.2
Percent female in occupation	19.52	23.70	0.3	0.3	0.3
Nurturant skill in occupation	-0.02	-0.23	-1.9	-1.3	-1.7
Cognitive skill in occupation	0.15	-0.70	4.4	9.2	5.5
Industry position (periphery = 1)	0.49	0.50	0.2	0.3	0.2

[a] Decomposition assesses percent of the natural log of hourly earnings gap between blacks and whites explained by race differences in means on each variable. Slopes used are those in Table 1.

SOCIAL FORCES

AN INTERNATIONAL JOURNAL OF SOCIAL RESEARCH
ASSOCIATED WITH THE SOUTHERN SOCIOLOGICAL SOCIETY

VOLUME 74: NUMBER 2 DECEMBER 1995

SF AUTHORS' GUIDE

Revised February 1994

IN GENERAL

1. Mail manuscripts (5 copies) to: **Social Forces**, Department of Sociology, Hamilton Hall, University of North Carolina, Chapel Hill, NC 27599-3210.
2. The paper must not be submitted to another journal while under review by SF.
3. Enclose a $15 processing fee. Papers are not reviewed until this fee is paid. The fee is waived for papers solely by currently enrolled students.
4. Manuscripts are not returned to authors.
5. Authors transfer copyright to SF. Permission fees for reprint of articles are split between authors and journal.

PREPARATION OF MANUSCRIPTS

1. For review, papers may be submitted in the form used by SF, American Sociological Association or other major sociological journals. Authors of accepted manuscripts are responsible for putting them into SF form.
2. **Format, Organization, and Style** Submit 5 clearly legible copies on 8 ½ by 11 good quality white paper. Double space typing throughout. For an accepted paper being revised to fit SF style, leave at least 1" margins; do not justify margins if using a word processor.

i. **Order** Organize the manuscript in this order: cover page; abstract; text; endnotes; references; tables; figures.

ii. **Cover Page** Give title; author(s); affiliation(s); and a footnote (*) indicating name and address of the author to whom requests for offprints or other correspondence should be sent ("Direct correspondence to ___") and acknowledgment (if any) of financial or other assistance.

iii. **Abstract** On a separate page, preceding the text, write a summary, 125 or fewer words (70 or fewer for a Research Note).

iv. **Endnotes** Use only for substantive comments, bearing on content. Number consecutively from 1, double space, and append on a separate page.

v. **Tables** Type each table on a separate page. Insert a location note — "Table 1 about here" — in the text. For substantive footnotes relating to a table or figure use lowercase letters. Use tabs to separate columns.

vi. **Figures** Must be artist-drawn, camera ready. Do not send original copy with a manuscript submitted for review. For review, figures may be roughly drawn but they must be neat and legible. For footnotes to figures, use same symbols as for footnotes to tables.

vii. **Mathematical Symbols** (and others likely to be obscure to compositor) Clarify with encircled words written in the margin.

viii. **References in Text** Indicate sources as illustrated below:

1. when author's name is in text — Lipset (1960); when author's name is not in text (Lipset 1960)
2. use page numbers only for direct quotations or specific notes or table — (Braudel 1969:213-14)
3. for more than 3 authors use "et al."
4. with more than 1 reference to an author in the same year, distinguish them by the use of letters (a,b,c) with year of publication (1975a)
5. earlier publication should precede later publication in brackets with parentheses (Tocqueville [1835] 1956)
6. enclose a series of references — in alphabetical order — in parentheses, separated by semicolons (e.g., Adler 1975; Adler & Simon 1979; Anderson, Chiricos & Waldo 1977; Bernstein et al. 1977, Chesney-Ling 1973a, 1973b).

ix. **References Following Endnotes** List authors alphabetically, by surname. For authors with more than one work cited, list works earliest to latest. For articles, next give title of article (caps and lower case), name of journal, volume number, and pagination. For books and monographs, give title, followed by publisher.

x. **Format of References**

Please spell out the first names of all authors and editors, unless they use only their initials or a first initial and a middle name in the source cited (e.g., Paul Radin, T.S. Eliot, and J. Owen Dorsey).

Elder, Glen H. 1975. "Age Differentiation and the Life Course." Pp. 165-90 in *Annual Review of Sociology*. Vol. 1, edited by Alex Inkeles, James Coleman, and Neil Smelser. Annual Reviews.

Myrdal, Gunnar. [1944] 1962. *An American Dilemma*. Harper & Row.

BOOK REVIEWS

The Thomas Theorem and The Matthew Effect*

ROBERT K. MERTON, *Columbia University and Russell Sage Foundation*

Eponymy in science is the practice of affixing the names of scientists to what they have discovered or are believed to have discovered,[1] as with Boyle's Law, Halley's comet, Fourier's transform, Planck's constant, the Rorschach test, the Gini coefficient, and the Thomas theorem.

This article can be read from various sociological perspectives.[2] Most specifically, it records an epistolary episode in the sociointellectual history of what has

[1] The definition of *eponymy* includes the cautionary phrase, "or are *believed* to have discovered," in order to take due note of "Stigler's Law of Eponymy" which in its strongest and "simplest form is this: 'No scientific discovery is named after its original discoverer'" (Stigler 1980). Stigler's study of what is generally known as "the normal distribution" or "the Gaussian distribution" as a case in point of his ironically self-exemplifying eponymous law is based in part on its eponymous appearance in 80 textbooks of statistics, from 1816 to 1976.

[2] As will become evident, this discursive composite of archival documents, biography of a sociological idea, and analysis of social mechanisms involved in the diffusion of that idea departs from the tidy format that has come to be prescribed for the scientific paper. This is by design and with the indulgent consent of the editor of *Social Forces*. But then, that only speaks for a continuing largeness of spirit of its editorial policy which, back in 1934, allowed the ironic phrase "enlightened Boojum of Positivism" (with its allusion to Lewis Carroll's immortal *The Hunting of the Snark*) to appear in my very first article, published in this journal better than 60 years ago.

** I am indebted, once again, to Harriet Zuckerman, Robert C. Merton, Cynthia Fuchs Epstein, David L. Sills, and Stephen M. Stigler for vetting a manuscript, to Jennifer Lee and Maritsa Poros for research assistance, and to Eugene Garfield for aid of other kinds.*

 Social Forces, December 1995, 74(2):379-424

come to be known as "the Thomas theorem":[3] "if men define situations as real, they are real in their consequences" (Thomas & Thomas 1928:572). More generally, that episode provides a strategic research site for examining certain substantive and methodological problems in the sociology of science. From the methodological perspective, it provides a prime example of the basic if presumably obvious precept that it is one thing to establish a phenomenon (i.e., show that something is empirically the case) and quite another to explain it. Obvious this may be but, as we shall see, the two are nevertheless easily (and, I believe, often) conflated. The episode also exhibits the risks involved in reductionist, single-factor explanations of a concrete social phenomenon (which becomes even more marked in *ex post* than in *ex ante* explanations). Finally, the episode provides an apparent instance of how sociocultural contexts of science and scholarship — in this case, the belated thrust of the civil rights movement toward equity for women — can make for an exclusive and premature interpretation that a particular cognitive phenomenon is sexist.

The cognitive phenomenon in this case consists of sociologists' frequent ascription of the Thomas theorem solely to W.I. Thomas rather than to both W.I. and Dorothy Swaine Thomas. I should emphasize from the start, however, that there is only incidental interest here in trying to adjudicate proprietary claims to this basic sociological idea, although the introduction of private archival materials may contribute to that result. Rather, the widespread accreditation of the Thomas theorem to W.I. Thomas alone holds interest for us here principally as a specific instance of a generic phenomenon in the reward-system of science and scholarship — what can be conveniently described as "the partial citation phenomenon," thus substituting four words for the approximately 20 words of its definition, i.e., the widespread accrediting by scientific and scholarly peers of an (actually or apparently) joint contribution to only a subset of the collaborators.[4]

Some forms of the partial citation phenomenon almost provide their own, intuitively evident, explanations. The partial citation of coauthors is hardly problematical, of course, for the rapidly increasing number of scientific articles,

---

[3] As I have noted elsewhere (Merton 1984:282), the designation Thomas *theorem* "does not, of course, adopt the term *theorem* in the strict mathematical sense (as, say, with the binomial theorem). It refers, rather, to an idea that is being proposed or accepted as sound, consequential, and empirically relevant." In proposing the Thomas eponym for both mnemonic and commemorative purposes (Merton [1942] 1973:273), I had fastened on the term *theorem* rather than such less formidable terms as *dictum, maxim, proposition*, or *aphorism* in order to convey my sense that this was "probably the single most consequential sentence ever put in print by an American sociologist" (Merton 1976:174). In any case, the word *theorem* was rhetorically employed in the same broad sense that had the mathematically minded Hobbes referring in *The Leviathan* to "general rules, called theorems or aphorisms." (Reading this note, the mathematical statistician, Stephen M. Stigler, reminds me that the redoubtable seventeenth-century mathematician John Wallis — he of the Wallis theorem — had ample cause to destroy the pretensions of the mathematically minded Hobbes to being an actual mathematician.)

[4] The word *citation* in the term *partial citation phenomenon* is to be construed broadly; not only as a formal reference in a note or bibliography but as any mode, including eponyms, of referring to previous scientific or scholarly work.

chiefly in the physical and biological sciences, with large numbers — at the extremes, literally hundreds — of listed coauthors (Science Watch 1995:1-2; Zuckerman 1968). Nor is it greatly problematical in cases of works by, say, four or five authors where the citation pattern of "et al." has long since evolved in the world of scholarship to serve the shared convenience of publishers, editors, senior authors, and readers (if not the neglected collaborators). Nor is it problematical that citations of large-scale research reports often have the institutionalized senior investigator alone eponymized, as with The Kinsey Report or The Coleman Report. But the partial citation phenomenon is surely problematical in the limiting case, as with the book in which the Thomas theorem first appeared, when only one of two authors is regularly cited.

The equitable peer ascription of contributions is no minor matter in the social institution of science which has evolved a reward system that consists basically in rewarding scientists by having knowledgeable peers grant them public recognition for their distinctive contributions. All other rewards flow from it.[5] And so it is that peers will experience and sometimes publicly express strong moral sentiments when they have reason to believe — as in the case of the Thomas theorem some have felt there is reason to believe — that the norm of rightful accreditation has been violated by systematically biassed ascriptions in the pertinent community of scientists. For like all other social institutions, the institution of science has its (partly manifest, partly latent) normative framework, one that includes the norm of *equity* in peer recognition of contributions.

Along with letters exchanged some time ago between Dorothy Swaine Thomas and myself, the core archival materials in this study of the allocation of credit for the Thomas theorem consist principally of a more recent exchange of letters between another pair of collegial sociologists which has one of them interpreting this instance of the partial citation phenomenon as a "piece of (dare I call it?) institutionalized sexism . . . in the new era." These letters — one of them, crisp and pointed by a social scientist of amply merited international fame; the other by myself, and replete with documentary exhibits running to a good-sized article in its own right — will be quoted verbatim.[6] As the more voluble member of that epistolary pair, I shall subject that exchange to analysis in terms of patterns in the growth and transmission of knowledge that I have been investigating over the years: such patterns as "establishing the phenomenon" and the use of "strategic research sites" (Merton 1987); "the retroactive effect" in perceiving or imagining adumbrations and anticipations of ideas in

[5]For the paradigm which maintains that the institutional dynamics of science derives from the interaction of its "reward system" and its "normative structure," see Part IV of Merton 1973.

[6]An apt procedure, one would think, since the sociological analysis of verbatim letters was introduced by W.I. Thomas and Florian Znaniecki; though, to be sure, on a rather larger scale running from page 217 to page 1114 of their classic work in five volumes, *The Polish Peasant in Europe and America* ([1918-20] 1927). For a critical examination of methodological problems involved in the use of letters in *The Polish Peasant*, see Blumer 1939:29-39.

the history of thought;[7] patterns of primary and derivative or serial diffusion of knowledge (Merton 1995); "socially organized skepticism" in the domain of science and scholarship (Merton [1942] 1973:267-78,339-40); the place of eponyms (such as the Thomas theorem) and of other forms of peer citation in the reward system of science (Merton [1942] 1973:273-74; [1957] 1973:297-302; 1988:619-23); "oral publication" as distinct from publication in print (Merton 1980); "multiples" or independent multiple discoveries and inventions (Merton 1973; Ogburn & Thomas 1922) and the emergence of citation analysis (Garfield 1955; Garfield, Sher & Torpie 1964). Above all else, however, the partial-citation phenomenon of the Thomas theorem will be analyzed in terms of the Matthew effect (Merton & Zuckerman [1968] 1973;1988).

This epistolary exchange which involves contesting interpretations of this one case of the partial citation phenomenon also raises normative questions about the peer recognition of scientific and scholarly contributions that provides the ultimate social and moral, if not the legal, basis of intellectual property in science (Zuckerman 1988a:526-27).

(As we have just seen in preview, such analysis in terms of one's enduring thematic interests in the sociology of science is bound, alas, to entail an intemperate abundance of self-citation. It is some consolation to note, however, that disciplined citation analyses do not mistake self-citation as evidence of the peer recognition that is the ultimate coin of the domain of science and scholarship.)

Diffusion of the Thomas Theorem

Like other important sociological ideas, the Thomas theorem has had its adumbrations and partial anticipations. Recognition of the subjective component in human action has had a long history in sociological thought and a far longer history before we sociologists arrived on the historical scene. Among the Ancients, we need only recall Epictetus (*The Encheiridion* [c. 110 A.D.] 1926-28: II, 487, §5), stating that "What disturbs and alarms man are not actions, but opinions and fancies about actions." And if one has not had occasion to read Epictetus recently, his aphorism (theorem?) may be recalled from the still enduring eighteenth-century masterwork, *Tristram Shandy*, where Laurence Sterne quotes it — in Greek of course — on the title page. And among the Moderns, there is Schopenhauer ([1851] 1974:I, 326) also echoing Epictetus[8] as he observes that "it is not what things objectively and actually are, but what they are for us and in our way of looking at them that makes us happy or unhappy." Be it said, however, that, as is generally the case with the *ex post*

[7] "Anticipations" refer to earlier ideas, formulations or findings that overlap later ones but do not focus upon and draw the same implications from them; "adumbrations," to earlier formulations or findings that, quite literally, foreshadowed later ones but only dimly and vaguely. On these patterns in the history of thought, see Merton [1949, 1957] 1968:13-25.

[8] Typically still for his time and place, Schopenhauer of course also echoed Epictetus in the original Greek and the derivative Latin rather than in his own native German.

spotting of adumbrations or anticipations, my having noticed those anticipatory passages is probably just another instance of the "retroactive effect" (in which undeveloped ideas that have remained in oblivion are later brought into the limelight only because new and clearly formulated ideas sensitize us to earlier, typically less developed, and previously ignored, versions).[9] The chances are that I would not have taken note of those aphorisms (theorems?) by Epictetus and Schopenhauer — as quoted even in the various editions of *Tristram Shandy* on my bookshelves — had it not been for a half-century of close familiarity with the Thomas theorem.

Along with these venerable anticipations, the theorem also had a striking contemporary and neighboring version. In his lecture course at the University of Chicago, W.I. Thomas's colleague George H. Mead had observed in distinctly sociological terms that "If a thing is not recognized as true, then it does not function as true in the community." But the Thomas theorem and the Mead theorem experienced notably different cognitive fates. In virtually self-exemplifying style, the Mead theorem dropped into permanent oblivion even after its posthumous transition from "oral publication" in lectures to publication in print (Mead 1936:29). Not so with the Thomas theorem.

True, no notice of the theorem was taken in any of the reviews of *The Child in America* that appeared in the three principal American sociological journals of the time — the *American Journal of Sociology* (which was then not only produced and edited at the University of Chicago but was also the official journal of the American Sociological Society), *Social Forces* (at the University of North Carolina), and *Sociology and Social Research* (at the University of Southern California). But soon afterward, as we shall have occasion to see in detail, Kimball Young, the prolific author of textbooks in social psychology and sociology then at the University of Wisconsin, gave the theorem special notice by selecting it as an epigraph for chapters in two successive textbooks; one, in his widely adopted *Social Psychology* (Young 1930:397) and the other, in his edited volume, *Social Attitudes* (Young 1931:100). The Young epigraphs evidently become an early conduit for diffusion of the quoted sentence. At any rate, the very next year, the omnivorous sociologist Howard [P.] Becker, was interpolating the sentence twice in his amplified and Americanized edition of Leopold von Wiese's *Allgemeine Soziologie* ([1924] 1932:34,79) and faithfully reporting that it was being quoted from Young's *Social Psychology*.

As is often the way with the genealogy of ideas, various types of errors began to intrude with enlarged diffusion. Omnivorous reader though he was, Becker managed to commit a triple error when a dozen or so years later he ostensibly located the Thomas sentence on page 79 of the condensed one-volume edition of the Thomas and Znaniecki masterwork, *The Polish Peasant in Europe and America* ([1918] 1927), where it is not to be found. Not content with this mishap, Becker advanced the extraordinary conclusion that this nonexistent ghost appearance was "in content at least . . . probably Znaniecki's," this even

---

[9]"Undeveloped ideas" inasmuch as these earlier adumbrations or anticipations were not singled out, elucidated, or followed up by further theoretical or empirical inquiry, either by their original authors or by others.

though the concept of "definition of the situation" had appeared before *The Polish Peasant* and then endured continuously as basic in Thomas's conceptual framework but did not turn up at all, Polish colleagues assure me, in Znaniecki's early work and surely not in his later work in English.[10]

The Barnard sociologist Willard Waller (1938:20) introduced an error of another kind in the course of diffusion. He misquoted the Thomas dictum, understandably without citing its specific source, thus: "As Thomas has put it, 'If *people* define *things* as real, they are real in their consequences.'" In our own time of acute sensitivity to deliberately or unwittingly gendered terms, one is at first tempted to interpret Waller's substitution of *people* for *men* as a quiet but deliberate effort to de-gender the theorem. However, as one notices the further substitution of *things* for *situations*, it seems more likely that the de-gendering was the inadvertent result of a faulty memory.[11]

In the same year as Waller's would-be quotation, an effort was made to pinpoint the lucid and elegant character of the formulation by describing it as "W.I. Thomas's sociological theorem" (Merton 1938:333). Like Young's quotations of the theorem, this almost casual allusion made no precise reference to the original source of what soon became abbreviated as "the Thomas theorem." The long-standing and largely continuing absence of such specific citations and texts persuade me that the widely neglected paragraphs which culminated in the Thomas theorem both require and merit repetition here. We note that the theorem caps the methodological case being made for use of

> The behavior document (case study, life-record, psychoanalytic confession) [which] represents a continuity of experience in life situations . . .
>
> [E]ven the highly subjective record has a value for behavior study. A document prepared by one compensating for a feeling of inferiority or elaborating a delusion of persecution is as far as possible from objective reality, but the subject's view of the situation, how he regards it, may be the most important element for interpretation. For his immediate behavior is closely related to his *definition of the situation*, which may be in terms of objective reality or in terms of a subjective appreciation — 'as if' it were so. Very often it is the wide discrepancy between the situation as it seems to others and the situation as it seems to the individual that brings about the overt behavior difficulty. To take an extreme example, the warden of Dannemora prison recently refused to honor the order of the court to send an inmate outside the prison walls for some specific purpose. He excused himself on the ground that the man was too dangerous. He had killed several persons who had the unfortunate habit of talking to themselves on the street. From the movement of their lips he imagined that they were calling him vile names, and he behaved as if this were true. *If men define situations as real, they are real in their consequences* (Thomas & Thomas 1928:572; italics added).

As we see, this essentially methodological observation draws upon the basic substantive concept of "defining the situation" which Thomas (1923:42-43;

---

[10]This statement will surely not be taken to detract from Znaniecki's major contributions to sociology which, however, were of quite other kinds than that represented by the theorem. My own appreciation of those contributions is summarized in Merton 1983.

[11]On the phenomenon of unintended gendering and de-gendering of language, see Merton, "De-Gendering 'Man of Science,'" 1996.

1929:1-13) plainly regarded as his most significant contribution to the socio-psychological understanding of the formation of social personality and character. Seen in its immediate context, the memorable theorem turns out to be a generalization of a specimen of paranoid behavior. (As we shall also see in due course, Thomas largely confined himself to reiterating this example the only two other times he himself quoted the theorem, a singular circumstance that raises an obvious problem for future exploration).

The longtime absence of a correct reference to the source of the theorem in sociological writings quoting it also led me to conclude some time ago that it had become known to American sociologists and their students largely if not entirely through secondary discussions in print rather than through their having read the original text. This assumption was reinforced by inquiries over the years from colleagues near and far which, we shall see, asked for the exact source of what had been described and analyzed as "the Thomas theorem" in "The Self-Fulfilling Prophecy" (Merton 1948). How such secondary diffusion came to be and, in particular, how social mechanisms of *initial* diffusion operated through such pathways as sociocognitive networks will be examined in the last part of this article as we explain sociologically the early absence of precise citations to the theorem and how that in turn helped produce the partial citation phenomenon.

That once conjectural assumption that the theorem had largely become known through secondary sources has now been empirically confirmed in a study by R.S. Smith (1993) of "well over 100 introductory textbooks" of sociology which found only one of the 40 texts that quoted or paraphrased the theorem citing its source, replete with page number, while an unspecified number of authors actually cited "The Self-Fulfilling Prophecy" as a mediating source. Smith also found that most of the textbooks attributed the theorem to W.I. Thomas alone and the few that referred to the book in which the theorem appeared generally failed to cite Dorothy Swaine Thomas as its second author. These empirical findings led Smith to a type of judgment which we have noted is deeply imbedded in the normative framework of science about equity in scholarly attributions:

> [S]ince it [the theorem] appears in a co-authored work, and no particular author is singled out as having written Chapter XIII [in which the theorem appears], it seems reasonable to suppose either author could have written this phrase. Consequently, *unless there is compelling evidence to the contrary,* it would seem proper scholarly practice to attribute these words to both W.I. Thomas and Dorothy Swaine Thomas (Smith 1993; I have inserted italics to underscore the scholarly care with which Smith allows for the possibility of countervailing evidence).

Having reported his empirical findings and having arrived at his contingent normative judgment, Smith goes on to propose possible explanations of this

> widespread practice of excluding Dorothy Swaine Thomas in referencing the theorem. This might be explained by poor scholarship on an individual level, although several of those involved are nationally and even internationally known authors. It can also be explained in terms of a structural issue — the genderization of the discipline as part of the process of professionalization. By not citing Dorothy Swaine Thomas these authors help sustain a view of sociology as historically a male domain (Smith 1993).

However, in mounting this crisp study of "Dorothy Swaine Thomas and the 'Thomas Theorem'" Professor Smith could not possibly have known that both his normative observation about the proper citation of coauthored work and his structural hypothesis of what might have led to the almost exclusive ascription of the eponymous theorem to the male Thomas at the expense of the female Thomas had been independently and concisely stated, without benefit of systematic empirical study, in a letter written some five years before by a social scientist of amply merited international fame.

The Imputation of "Institutionalized Sexism"

That letter, addressed not to me but to David Sills, with whom I was then collaborating on the volume *Social Science Quotations* (Sills & Merton 1991), holds varied historical, methodological, and sociological interest as it briefly describes a search for "the original source of the Thomas theorem." It bears not only upon the early history of this important sociological idea but also upon the methodological requirement of putting to empirical test *ex post* hypotheses evoked by data that are, of course, initially congruent with them. Moreover, as I have hinted, the plainly informal letter and my lengthy thematic responses to it exemplify various patterns in the transmission of knowledge that I had been exploring for some time. Not least in point, the letter culminates in the composite normative and explanatory conclusion that ascribing the theorem to W.I. Thomas alone amounts to sexist eponymy.

Here, then, is the short evocative letter in its verbatim entirety.

August 16, 1988

David Sills
Social Science Quotations
111 Eighth Ave., Suite 1503
New York, NY 10011

Dear David,

I should have the X . . . and Y . . . citations to you shortly. In the meantime, I bring to your attention an interesting footnote in the sociology of sociology. About eight months ago, I was desperately looking for the original source of the Thomas theorem. I could find it nowhere, except in Merton who used it without a footnote. I finally was about to resign myself to using as my citation: Cited in Merton, etc. Then your little brochure, "Social Science Quotations: Guidelines" arrived, and lo and behold, on p. 15, as one of your examples, you use the Thomas theorem, with a proper citation.

Well trained as I am in scholarly skepticism of sources, I took out the book from the library. And lo and behold, you are in error, an error which not only you but Merton and indeed the entire U.S. (world?) scholarly community have made consistently. For the book was <u>not</u> written by W.I. Thomas, but by William I. and Dorothy Swaine Thomas. Nothing in the book indicates that he wrote some chapters and she others. They are joint authors. And, at least in Social Science Quotations, this piece of (dare I call it?) "institutionalized sexism" should not be perpetuated.

Yours in the new era,

[I anonymize the author of this informal note as "Skeptical Social Scientist" (hereafter SSS)]

Patterns in the Transmission of Scientific Knowledge

Although this letter was addressed to David Sills, I undertook to respond to it since I was the one who had long ago elected to attribute the theorem exclusively to W.I. Thomas and since, as coeditor of *Social Science Quotations*, I had prepared the entry on the theorem as a specimen quotation in the "Guidelines" for contributors to that volume. I soon found myself resonating to the considerable array of cognitive and normative ideas and problems packed into the brief but complex letter that exemplified diverse patterns in the normative framework of science and the transmission of scientific knowledge. Herewith, then, a few of those patterns.

PATTERNS OF KNOWLEDGE DIFFUSION

To begin with, it will be noticed that SSS matter-of-factly adopts the eponym "Thomas theorem" which had been introduced a half-century before to signal the assessed importance of the reverberating Thomas sentence. It is unlikely, however, that SSS had come upon that eponym where it first appeared since that was in an article published long ago (Merton 1938) in the *Philosophy of Science*, a journal presumably not often read by social scientists of a much later time. Nor is it likely that this same social scientist writing in the late 1980s would have come upon the eponym in 1948 when the theorem was being analyzed and distinguished from the related concept of "The Self-Fulfilling Prophecy" in *The Antioch Review*, another journal not notable for its social science readership. I am inclined to believe, therefore, that like those others who had let me know that this was the case for them, SSS had come upon the eponym in one or another of the three editions of *Social Theory and Social Structure* (Merton 1949, 1957, 1968) which had included both those articles. In accord with the R.S. Smith (1993, 1995) finding that this book had become something of a conduit for the Thomas sentence, here is SSS "desperately looking for the original source of the Thomas theorem" and about to adopt what some might describe as the honorable but, for many, the also unappetizing expedient of quoting from a mediating source; to wit: "Cited in Merton, etc." (just as we have seen Howard P. Becker do some 60 years before in quoting the theorem via Kimball Young). As indicated by SSS and others, this citational expedient had resulted from the continued absence of any precise reference to the original source in all three editions of *Social Theory and Social Structure*.[12] Fortunately, SSS informs us, *Guidelines for Contributors to Social Science Quotations* came along in the nick of time to provide "a proper citation."[13]

---

[12]As we shall see from archival evidence yet to be examined, both adventitious and theoretical reasons made for this studied failure to supply the originally well-known reference to the exact source of the Thomas theorem in *The Child in America*.

[13]This, then, may have been the first anticipatory case, even before publication, in which *Social Science Quotations* fulfilled a manifest function that was described this way: "Of obvious use to readers coming upon quotations new to them, exact references may also prove useful for swiftly locating the more familiar quotations. By leading readers back to the sources, such detailed references can help them place even extended quotations in their larger contexts. In

Although this straightforward scholarly letter reports full familiarity with the substance of the Thomas theorem and with the eponym, it makes clear that such knowledge did not derive from having read the original formulation. Thus, the letter provides a distinct case of the basic difference between the *primary and the derivative or serial diffusion of ideas,* a subject of distinct interest to those of us at work on patterns of diffusion in science and technology (Coleman, Katz & Menzel 1966; Merton 1989, 1995; Rogers [1962] 1995; Zuckerman 1989). When a first-hand quotation does not provide an exact citation to its source, it cannot, of course, make for independent recourse to the original source and later derivative or serial diffusion can only reproduce the quotation as mediated. This, in turn, raises the sociological as well as normative question, which is here only introduced rather than explored: how does it happen that, unlike SSS who was ready to cite the mediated source, many of the authors who were plainly quoting the theorem derivatively rather than directly have not done so? In short, is there a norm for citing mediated references and if not, why not?

Is There A Norm for Citing Mediated References?

SSS's announced intention of citing his mediating source of the Thomas theorem may be defined by some peers as supererogatory, for there are evidently no well-established norms governing such citation behavior. At least, not if one may judge from the comparative rarity of citations to encyclopedias and other reference works in scholarly publications. Or more specifically, if one may judge from the frequency with which even mature scientists and scholars have written sociologists of science to ask whether or how to ascribe "proper credit to an author for drawing one's attention to a valuable reference."[14]

These normative questions about mediated references had not yet crystallized back in mid-century when the sometime sociologist of science Norman Kaplan (1965) introduced the generic problem of "the norms of citation behavior." Nor have these questions about *mediated references* yet been examined by the founder of the *Science Citation Index* and of citation analysis, Eugene Garfield (1983, 1995), in his longtime and still ongoing examination of how the norms and practices of citation are acquired. (See also Cronin 1984.) However, we now see how this detail in the collegial letter from SSS tacitly directs us to a generic, difficult, and important sociological problem: the dynamics of the emergence of a new social norm; (on the generic problem, see Coleman 1990). Just as another detail tacitly directs us to the institutionalized norm of socially organized skepticism.

---

this way, a book of quotations can extend an open invitation to the further reading or rereading of the original texts, beyond the quotations themselves" (Sills & Merton 1991: xvi).

[14]For example, the query quoted in the text which was addressed in the first instance to Eugene Garfield and derivatively to me by the author of "Thoughts on Eponyms," Howard B. Burchell, M.D. (1985).

SOCIALLY ORGANIZED SKEPTICISM

Having long ago identified this technical and moral norm embedded in the culture and the social structure of science (Merton [1942] 1973:267-78;339-40), I can only applaud SSS's manifest adherence to it. The term and concept, *socially organized skepticism,* refers to institutionalized arrangements for the critical scrutiny of knowledge claims in science and learning that operate without depending on the happenstance skeptical bent of this or that individual. The process of socialization in the culture of science joins with such social arrangements as published and unpublished "peer review" that serve as agencies of social control which see to it, among other things, that authors generally abide by the norm of indicating their predecessors and sources. That norm has many cognitive and social functions; Garfield (1983, 1995) lists 15 of them. Among the manifest cognitive functions are those of enabling scientists to consult prior sources to see whether they have been correctly utilized and whether they also provide pertinent information not included in the mediating source. A manifest social function is to pay homage to pioneers and other predecessors, along with its largely latent and correlative function of thus helping to maintain the reward system of science which, like all institutional reward systems, initiates or reinforces incentives for role performance.

Exemplifying socialization in this normative practice of organized skepticism, this committed scholar reports "having been well trained . . . in scholarly skepticism of sources," and goes on to use the secondary work of *Social Science Quotations* as a means of getting to the original source of the Thomas theorem that can then be examined at first hand. This soon led SSS to the discovery that the book in which the theorem first appeared was actually written by William I. Thomas *and* Dorothy Swaine Thomas and that, in turn, led (as we have seen that, in effect, it later led R.S. Smith) to the conclusion that ascribing the theorem to W.I. Thomas alone amounts to "institutionalized sexism."

This suggests the hypothesis that such a conclusion is especially apt to be drawn in a time of socially and culturally induced sensitivity to all manner of discriminatory and exploitative -isms. For, as the sociology of science has noted from its earliest days, "the question of the relative importance of intrinsic and external factors in the determination of the foci of scientific interest has long been debated" (Merton [1938] 1970:199) but there is no question that social and cultural contexts do variously influence problem-choice and hypothesis-choice (Zuckerman 1978, 1994). In that process, certain contextually influenced hypotheses rather than others soon leap to mind as plausible. In this case, it appears, the context-laden hypothesis that the failure to ascribe the Thomas theorem to both Thomases must be an expression of sexism. But of course that hypothesis raises the methodological question whether joint authorship of the book in which the theorem first appeared is enough to conclude that the theorem was itself a joint product. In self-exemplifying style, the cognitive norm of socially organized skepticism thus requires us in turn to examine that conclusion by probing other scholarly sources and personal archives, as we shall be doing in due course.

Meanwhile, one can see from the SSS letter how adherence to the norm of organized skepticism can lead to gratifying experiences that presumably

reinforce continuing adherence to it. Not least, the special pleasure that comes from erasing errors in received knowledge. For the detection of long-accepted error also has its social and personal functions. It not only contributes to the common wealth of science but results in system-induced heightened esteem by knowing colleagues. I too once found myself resonating to the kind of Eureka glow that evidently came to SSS upon discovering the unscholarly error that "not only [Sills] and Merton [but] indeed the entire U.S. (world?) scholarly community have made consistently." I still recall the scholarly thrill of first tentatively spotting and then actually demonstrating a centuries-long error in received scholarship. As it happens, this episode also involved the correct ascription of a memorable sociocultural aphorism (theorem?) to its actual author(s). The aphorism "If I have seen further, it is by standing on the shoulders of giants" — which had diffused widely in the literary as well as the scientific community, especially after it became known that Isaac Newton once made it his own — had long been ascribed to what I demonstrated was a phantom source in a work by the ancient poet Lucan rather than to its actual author, the twelfth-century Bernard of Chartres. Much along the same lines that SSS feared might be the case with the ascription of the Thomas theorem to W.I. Thomas alone in the then forthcoming Sills and Merton reference book, *Social Science Quotations,* the ubiquitous reference book Bartlett's *Familiar Quotations* had been perpetuating the error of an ancient source for the Newton aphorism — this, in no fewer than seven editions for almost a century. In the latter case, it became a scholar's comfort to find that even in this postmodern age of deconstruction, evidentiary truth can still prevail. For I can happily report that only thirty years or so after that ghastly error of a ghostly source had been demonstrated in *On the Shoulders of Giants* (Merton [1965,1985] 1993:246-60), it was finally corrected in the fine sixteenth edition of Bartlett's ([1882] 1992:281b) by its new scholarly editor, Justin Kaplan. And, in accord with the norm governing scholarly acknowledgment, the correction was made with due reference to that long drawn-out and digressive documenting work of mine.

But if the editor of Bartlett's *Familiar Quotations* saw the light and rectified what had been laboriously shown to be a fossilized error of faulty scholarship, not so, it appears, with the editors of *Social Science Quotations.* In unyielding style, they decided to continue ascribing the Thomas theorem to W.I. Thomas alone. This, despite the advance warning by their colleague-at-a-distance that to do so would not only perpetuate an almost universal error of quite unscholarly attribution but would amount to a "piece of 'institutionalized sexism.'" As we shall soon see in detail, that apparently intransigent decision was based on fortunate access to a personal archive.[15]

---

[15]This, however, is manifestly the place to anticipate the detailed documentary analysis a bit by replicating a memorandum on this decision dated "26 December 1989":

THE THOMAS THEOREM
Canonical Version

To: David
From: Bob

It seems to me that we should give readers or browsers the fruits of our unique documented knowledge that though the theorem appeared in the jointly written *The Child in*

Those recent observations by SSS and R.S. Smith on seeming inequities in the citation history of the Thomas theorem provide yet another specimen of a recurrent pattern in the domain of science and scholarship, to wit the pattern of multiple independent observations, discoveries, and inventions.

The Pattern of Multiple Independent Observations, Discoveries, and Inventions

As is well known, a longstanding theory of the development of science and technology is rooted in the theoretically strategic fact of the multiple and independent appearance of essentially the same scientific observation, discovery or invention; what, for brevity's sake, can be described as a "multiple" (Merton 1961, 1963). This pattern of independent multiples has been found to hold for all manner of cognitive contributions, ranging from the great through the intermediate and small to the trivial. An apparent example of the truly trivial multiple is provided in the triply independent observations by SSS (1988), Smith (1993), and myself (Merton 1976, [1948] 1982) that the Thomas theorem was being ascribed solely to W.I. Thomas, typically without even collateral reference to Dorothy Thomas. To situate the specific empirical case in theoretical terms, the widespread citation pattern of the Thomas *theorem* was identified at the outset of this retrospective article as an instance of the partial citation phenomenon — the delimited accrediting of a presumably joint contribution to a subset of the collaborators.[16] Whether this example of a multiple in the ongoing history of the Thomas theorem is as *theoretically* trivial as it is surely empirically trivial will become evident only upon examining the apparent counter-example of the typically full rather than partial citation of the important Ogburn--[Dorothy] Thomas (1922) paper on independent inventions. (On "the trivial and the important in sociology," see Merton [1961] 1973:59-62; 1987:16-19].)

America, it was nevertheless written solely by W.I. I won't burden you with another copy of the 14-page gloss on that fact when we were accused of 'institutionalized sexism' in having ascribed it wholly to W.I. in the Guidelines to Contributors.

I believe that the quotation should be ascribed to W.I. just as it is in the Guidelines. Plainly, a more extended arrow [our idiomatic term for explanatory notes appended to quotations] is needed to explain the lone ascription. It might read this way:

The Child in America 1928:572 — Although the 'Thomas theorem' appears in this book written jointly by W.I. Thomas and Dorothy Swaine Thomas, it is ascribed to him alone since Dorothy Thomas reported [insisted?] in a letter to one of the editors that she had done only the statistical portions of the book and that "the concept of 'defining the situation' was strictly W.I.'s."

Of course, this could be condensed — or extended!

[In the event, this explanatory note was neither condensed nor extended but substantially reproduced in *Social Science Quotations* .]

[16] As we shall see when we turn to the problem of explaining rather than merely identifying instances of the partial citation phenomenon, they often derive from the Matthew effect.

The Evocative SSS Letter in Retrospect and the RKM Letter in Prospect

SSS's succinct letter of 1988 along with the Smith oral publication of 1993 have thus provided much grist for the sociological mill as we focus on the normative question of proper ascription of the Thomas theorem. What SSS described as "an interesting footnote in the sociology of sociology" reflects various manifest and latent patterns of peer interaction that obtain within the institutional framework of science and scholarship. And as we shall now see, the extensive letter in response examines the *normative issues* raised by SSS, supplies previously unpublished archival evidence about the respective roles of W.I. and Dorothy S. Thomas in formulating the Thomas *theorem,* and addresses the theoretical and methodological problems involved in trying to explain this specimen of the *partial citation phenomenon.* It will come as no surprise, of course, to find that, like the SSS document, this one also exhibits patterns that have been identified in the sociology of science. And so, like the letter from SSS, herewith reproduced verbatim, it too will be subjected to ongoing commentary in discursive footnotes and bracketed text.

RKM TO SSS: A VERBATIM DOCUMENT ON THE THOMAS THEOREM AS AN INSTANCE OF THE PARTIAL CITATION PHENOMENON

SOCIAL SCIENCE QUOTATIONS

Who Said What, When, and Where

10 September 1988

Dear [SSS],

I want to add my thanks to David's for your willingness to put together a batch of quotations from X------ and Y-----. Knowing that I had been thinking of a much fuller annotation in SSQ for "The Thomas Theorem," David has asked me to respond to your "footnote in the sociology of sociology" concerning the proper attribution of the theorem. I'm glad to try my hand at that since it should help me move toward a proper annotation.

To begin with, you are surely not alone in having searched in vain for the prime source of the Thomas Theorem. As you say, I failed to give a specific reference when I first happened to refer to it as a theorem back in the 1930s and 40s. As a result, I've periodically received requests for the precise reference. I enclose such a fairly recent inquiry [as Exhibit 8], this one from Cynthia Epstein (who I know won't mind my including hers as a specimen document).

Now this is just the sort of information which David and I intend to have the scholarly apparatus of SSQ make instantly accessible. As you note, even our little

brochure, GUIDELINES TO CONTRIBUTORS, does provide "a proper citation" to the theorem. But then, having exercised a proper "scholarly skepticism of sources" by looking up the cited book source for yourself — this being the kind of behavior conforming to the norm of "organized skepticism" which I proposed as a major element in the social institution of science and scholarship back in the early 1940s — you go on to report your findings in these words:

Lo and behold, you [David Sills] are in error, an error which not only you but Merton [too] and indeed the entire U.S. (world?) scholarly community have made consistently. For the book was not written by W.I. Thomas, but by William I. and Dorothy Swaine Thomas. Nothing in the book indicates that he wrote some chapters and she others. They are joint authors. And, at least in the Social Science Quotations, this piece of (dare I call it?) 'institutionalized sexism' should not be perpetuated.

To make it clear that your observation registers a fairly newfound [general] sensitivity to the matter of sexism, you sign off as

"Yours in the new era,"

[It will be observed that in one respect, the otherwise clear-spoken Skeptical Social Scientist is here rather puzzling. Having noted in the first paragraph of the letter that the *Guidelines for Social Science Quotations* which Sills and I had sent along to potential contributors has "a proper citation" to the source of the Thomas theorem, that plainly assiduous scholar nevertheless goes on to declare that we, like "the entire U.S. (world?) community" have consistently erred in ascribing *the book* to W.I. Thomas alone. My response to this puzzle took this form:]

Now, you are altogether right of course in observing that the book in which the Thomas theorem first appears — THE CHILD IN AMERICA: BEHAVIOR PROBLEMS AND PROGRAMS (New York: Knopf, 1928) — was "not written by W.I. Thomas, but by William I. and Dorothy Swaine Thomas." Indeed, you will find that our SSQ brochure indicates as much in its list of sources of the specimen quotations on page 19. (It refers to W.I. and Dorothy S. Thomas, following the format of the INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES. But I allowed friendship to taint scholarly precision. All his friends referred to him as "W.I.", never as "William I." and W.I. clearly preferred that usage [as, we shall see, did his collaborator Dorothy]. But we should have cited him as he appears on the title page, not in this misplaced friendly but unscholarly fashion. As the editor of the IESS in which SOCIAL SCIENCE QUOTATIONS will appear as Volume 19, David may overrule me on this [as in the event, he did] since I note that the biographical entry in Volume 16 lists the book as having been written by W.I. Thomas and Dorothy S. Thomas. And I recall that the authoritative volume, edited by Ed Volkart for the Social Science Research Council back in the early 1950s, referred on the title page to the "Contributions of W.I. Thomas to Theory and Social Research," not to William I. Perhaps too many old friends of W.I. have improperly subordinated scholarship to friendship. But this is scarcely the matter central to our discussion. We are in thorough agreement, then, that the book was written by the two Thomases.

And you are also entirely correct in reporting that "Nothing in the book indicates that he wrote some chapters and she others. They are joint authors." There is nary a word in the book stating who thought or wrote what.

All this leads you to conclude that our ascribing the theorem to W.I. alone, rather than to both W.I. and Dorothy, is plainly a case of sexism which may become further institutionalized by the medium of SOCIAL SCIENCE QUOTATIONS. And you remind us that we have entered a new era where old-style sexism no longer goes.

Still, I am confident that as a scholar given to the careful sifting of fact from fable, you are ready to reconsider your initial interpretations in light of new evidence. In this case, your double indictment of David and me as guilty of scholarly error and of sexist bias to boot. With that in mind, I shall submit several[17] exhibits in the hope that you will want to withdraw both accusations (not that any of us are wholly free from error or immune from the contagion of inadvertent or of institutionalized bias).[18] For we both surely agree with those wise words of the 12th-century William of Malmesbury (much admired by my mentor, the dean of historians of science, George Sarton [1931, I:255] who wrote of him [that] "He was the best chronicler of his time; the first one after Bede who tried not only to chronicle events but to explain their causal relations"): "Throw out such dubious stuff and gird ourselves for a factual narrative." (Alas, my ancient notes fail to note the work in which this quotation [from Malmesbury] is to be found.)

Exhibit 1 *[The Thomas Theorem and the Matthew Effect]*

The first exhibit bearing on the case of the Thomas Theorem is drawn from my piece, "The Matthew Effect in Science," (SCIENCE, 5 January 1968, vol. 159, 55-63, as this was slightly amplified when reprinted in my collection of papers, THE SOCIOLOGY OF SCIENCE (University of Chicago Press 1973). By way of orientation, I should report that what I described as 'the Matthew effect' (after Matthew 13:12 and 25:29)[19] consists in the accruing of greater recognition by peers for particular scientific or scholarly contributions to scholars of great repute and the withholding of such recognition from [their collaborating] scholars who have not yet made their mark. Here it is being suggested that the Matthew effect might have operated in the very case which is of central interest to us at the moment. Thus:

> The problem of achieving a public identity in science may be deepened by the great increase in the number of papers with several authors in which the role of novice collaborators becomes obscured by the brilliance that surrounds their illustrious coauthors. Even when there are only two collaborators, the same obscurant effect may occur for the junior who exhibits several "inferiorities" of status. The role ascribed to a doubly or trebly stigmatized coauthor may be diminished almost to the vanishing point so that, even in cases of later substantial achievements, there is little recognition of that role in the early work. Thus, to take a case close to home, W. I. Thomas has often been described as the sole author of the scholarly book *The Child in America*, although its title page unmistakably declares that it was written by both William I. Thomas and Dorothy Swaine Thomas. It may help interpret this recurrent misperception to consider the status of the collaborators at the time the book was published in 1928. W. I.

---

[17]As the reader will soon notice, these documentary exhibits turned out to be a good many more than merely "several."

[18]SSS had no way of knowing that I would find this charge of potential "*institutionalized* sexism" particularly distressing. For it was back in the early days of the civil rights movement — a decade or so before the Civil Rights Acts of 1957 and 1960 — that I had attempted to identify and to analyze the social phenomenon of "*institutionalized* discrimination" as distinct from acts of discrimination by *individuals* (Merton 1948a: 120, 101). That had seemed to me a fundamental sociological distinction then as it seems to me still.

[19]By way of reminder: "Unto every one that hath shall be given, and he shall have abundance: but from him that hath not shall be taken away even that which he hath."

Thomas, then 65, was president of the American Sociological Society in belated acknowledgement of his longstanding rank as dean of American sociologists, while Dorothy Swaine Thomas (not to become his wife until seven years later) was subject to the double jeopardy of being a woman of sociological science and still in her twenties. Although she went on to a distinguished scientific career (incidentally, being elected to the presidency of the American Sociological Society in 1952), the early book is still being ascribed solely to her illustrious collaborator even by ordinarily meticulous scholars.[19]

19. See the ascriptions of the book, for example, in Alfred Schutz. *Collected Papers*, 2 vols., edited and with an introduction by Maurice Natanson (The Hague: Martinus Nijhoff, 1962), 1:348, n71; Peter McHugh, *Defining the Situation* (Indianapolis: Bobbs-Merill Co., 1968), p. 7.

Exhibit 2 *[Why I do not take the Alfred Schutz ascription of the book to W.I. alone as ipso facto evidence of a sexist bias]*

The preceding quoted footnote indicates that even so meticulous a scholar as Alfred Schutz (1962:I, 348, n. 71) has managed to ascribe the salient *book* solely to W.I. To obviate any need for you to search out the passage in which he does so and thanks to our home photocopier, I Canonize it here (as I should perhaps have done in the published note):

> The "definition of the situation" refers to the so-called "Thomas theorem" well known to sociologists: "If men define situations as real, they are real in their consequences." [71]
>
> 71 It was first developed by William Isaac Thomas, in his book, *The Child in America: Behavior Problems and Programs*, New York, 1928, p. 572. See also W. I. Thomas, *Social Behavior and Personality*, edited by E. K. Volkart, Social Science Research Council, New York, 1951, pp. 14 and 80ff.; the term "Thomas Theorem" was coined by Robert K. Merton, *Social Theory and Social Structure*, Glencoe, 1949, 179.

You will notice at once the emphatic though probably unintended way in which, the to-me admirable scholar, Alfred Schutz, casts Dorothy Thomas into limbo by ascribing not merely the Thomas Theorem but the book to W.I. alone. Indeed, the fateful masculine pronoun in the phrase "his book" would seem to lend grist for your mill of sexism at work in the case of the Thomases. Nevertheless, as you see from my reference to Schutz's error in attributing the book wholly to W.I., I do not impute a sexist bias that made for the error. The reason? Our now fairly extensive studies of the Matthew effect in collaborations among scholars of greatly differing standing in the field have found this to operate quite regularly among male collaborators and among female collaborators as well. (Which is not to say, of course, that sex or gender does not affect the probability of achieving recognition for one's scientific or scholarly work; the intensive studies of men and women scientists by Harriet Zuckerman and Jonathan Cole over the years being the

basis for that statement.)[20] In view of all this, I adopted the clinical hypothesis that Schutz's ascription of the book to W.I. alone was probably an instance of the Matthew effect rather than a sexist predilection.

Exhibit 3 [*Wherein I reiteratively ascribe the theorem to W.I. alone and absolve the theorem of total subjectivism*]

This exhibit has me [once again] emphatically ascribing the theorem, *not* the book, solely to W.I., even though it appeared in a co-authored book. This I have done regularly since its logical character and, I confess, its assessed importance first led me to describe it as "The Thomas Theorem". (This was not, as Alfred Schutz understandably cites it in his foregoing footnote, in 1949 but back in 1938. But then, there was not the least reason for this colleague at-a-distance to know that the term had appeared earlier in my article, "Science and the Social Order" [Merton 1938:331-332]).

You will note that the following passage, again photo-copied to save you confirming search, connects the theorem to other formulations but singles it out as the most succinct and memorable formulation of much the same sociological idea. But I must not digress into questions of sociological theorizing. Here, then, is a pertinent fragment [drawn] from a piece of mine titled "Social Knowledge and Public Policy," first published in 1975 and reprinted in Merton [1976]; the fragment appears on pages 174-175, 177:

> **The Hazards of Subjectivism**
>
> The idea of the subjective component in human action has a long history in sociology and had an even longer history before we sociologists arrived on the historical scene. It is an idea, moreover, that has been formulated in various traditions of sociological thought: in the notion of *Verstehen* (roughly: intuitive understanding) advanced by Max Weber (and many others influenced by him), Robert MacIver's "dynamic assessment," Florian Znaniecki's "humanistic coefficient," Talcott Parsons's "voluntaristic theory of action," and Schutz's "phenomenological perspective." The idea was succinctly formulated by W. I. Thomas in what is probably the single most consequential sentence ever put in print by an American sociologist:
>
> If men define situations as real, they are real in their consequences.[20]
>
> Now, it is one thing to maintain, with Weber, Thomas, and the other giants of sociology, that to understand human action requires us to attend systematically to its subjective component: what people perceive, feel, believe, and want. But it is quite another thing to exaggerate this sound idea by maintaining that action is *nothing but* subiective. That extravagance leads to sociological Berkeleyanism (the allusion being, of course, to the English champion of philosophical idealism, not to an American geographic or academic place). Such total subjectivism conceives of social reality as consisting *only* in social definitions, perceptions, labels, beliefs, assumptions, or ideas, as expressed, for example, in full generality by the criminological theorist, Richard Quinney, when he writes that "We have no reason to believe in the objective existence of anything."[21] A basic idea is distorted into error and a great injustice is visited upon W. I. Thomas whenever his theorem is thus exaggerated.
>
> Exaggeration of a seminal truth produces its own brand of error. Total subjectivism, which maintains that only social definitions of the

[20]Cole (1979), Cole and Zuckerman (1984), [Zuckerman, Cole and Bruer (1991), Zuckerman and Cole (1994)].

> situation (or other subjective equivalents) determine the character of human action and its consequences, in effect manages to transform the Thomas Theorem into this fallacious maxim:
>
> > If men do *not* define situations as real, they are not real in their consequences.
>
> . . .To correct the imbalance that comes with total subjectivism and to restore the objective components of social situations to their indispensable place, we plainly need this counterpart to the Thomas Theorem:
>
> > And if men do *not* define real situations as real, they are nevertheless real in their consequences.

You evidently consider this ascription of the theorem wholly to W.I. (with an allusion to Dorothy Thomas only in a footnoted citation to the book)[21] as *prima facie* evidence of "sexism." In this case, however, presumably an expression of personal rather than "institutionalized sexism." But I urge you to withhold reiteration of this harsh impeachment until you have examined Exhibits yet to come.

Exhibits 4 and 5 *[Which bear renewed witness to an longtime effort to deter the ascribing of sexism to scholars who attribute the theorem solely to W.I.]*

A few prefatory remarks before I introduce these almost identical exhibits.[22] Nearly six decades ago, I elected to focus on social structures, social patterns, and social processes in the domain of science and scholarship — not a subject of immense scholarly interest back then. And, as you surely have no cause to know, some thirty years ago I first tried to identify the institutionally distinctive reward system of that domain since it seemed to me to provide part of the dynamics and patterning of scientific work. That was set out in some detail in a longish paper titled "Priorities in Scientific Discovery"(1957). Part IV of THE SOCIOLOGY OF SCIENCE (1973), designated as "The Reward System of Science," collects a variety of my articles focussed on the workings of that system. Among other things, that 1957 piece proposed the strongly stated hypothesis that contradictions

---

[21] In retrospect, I note that SSS and, for that matter, R. S. Smith in his 1993 paper, along with countless others before and after them might have obviated their continuing search for the provenance of the theorem had they happened upon Volkart's reprinting of the concluding chapter back in 1951 (Thomas 1951) or even this citation to *The Child in America* in 1975. But as George J. Stigler 's (1961) seminal paper, "The Economics of Information" led us to see both in principle and in fact, even in our new age of advanced information-technology, achieving retrieval of sought-for information can exact prohibitive costs in terms of time, energy, or money.

[22] This archival essay-letter, which was plainly not intended for publication, had adopted "the non-linear, advancing-by-doubling-back Shandean Method of composition" inaugurated by Laurence Sterne in his immortal eighteenth-century *Tristram Shandy* and hesitantly adapted, just two centuries later, in my own "Shandean Postscript," *On the Shoulders of Giants* (which, it may be remembered, turned up in the introductory pages of this paper as I was empathically resonating to the manifest pleasure expressed by SSS upon discovering what was taken to be the universal error of attributing the Thomas theorem to W.I.). Sterne's *Tristram Shandy* had drawn upon the technique of "stream of consciousness" long before William James had formulated that apt metaphoric concept in his monumental *Principles of Psychology* ([1890] 1950, I: 239) and longer still, before James Joyce and, to a degree, Virginia Woolf had put that technique to work in their novels.

between the reward system and the normative system of science made for such social pathologies as the occasional felonies of plagiarism and the creation of fraudulent data. (I stray from the subject in hand to mention this only because of the intense current interest, both scholarly and popular, in such pathological phenomena in science. Back in the 1950s, that effort to identify the varieties of misbehavior in science and to theorize about their systemic sources apparently seemed like little more than sociological muckraking.)[23]

Back to our immediate subject, I also report that Part V of the same volume, THE SOCIOLOGY OF SCIENCE, is given over to an examination of "The Processes of Evaluation in Science." As one would suppose, it includes the article on the Matthew effect and other pieces devoted to theoretically derived and empirically investigated patterns of [peer] recognition in science.

I report these longstanding interests, in supremely egocentric style, for a reason. These ¶s are designed to provide a context for the pair of exhibits, 4 and 5. From that context it can be inferred that I've had more than a friendly and ad hoc interest in the peer perceptions of my old, much admired, friends, W.I. and Dorothy Thomas. And so, as [the preceding exhibit and] those [following] exhibits testify, I have gone into print, from time to time, to get the story straight about the source of the Thomas Theorem.

The essential step, it seemed to me in light of certain patterns that occasionally emerge in the world of scholarship, was to provide a kind of anticipatory prophylaxis,[24] in print, directed against easy misinterpretations and harsh indictments of scholars who attributed the theorem to W.I. rather than to both W.I. and Dorothy. Perhaps getting the facts in print would preclude such indictments based on skimpy *prima facie* evidence. Thus:

Exhibit 4 *[Evidence that my own attribution of the Thomas Theorem to W.I. alone was neither 'sexist' nor a case of the Matthew effect]*

> 20. What we may call the Thomas Theorem appears just once in the corpus of W. I. Thomas's writings: on page 572 of the book he wrote with Dorothy Swaine (Thomas) Thomas entitled *The Child in America* (New York: Knopf, 1928). I ascribe the theorem to W. I. Thomas alone rather than to the Thomases jointly not because of his gender or great seniority but only because Dorothy Thomas has confirmed for me what many have supposed: that the sentence and the paragraph in which it is encased were written by him. There is thus nothing in this attribution that smacks of "the Matthew Effect," which in cases of collaboration between scholars of decidedly unequal reputation has us ascribe all credit to the prominent scholar and little or none to the other collaborator(s). On the Matthew effect. see Merton, *op. cit.*, 1973, Chapter 20.

(This wouldbe prophylactic footnote is quoted from the second 'edition' of the previously cited paper, "Social Knowledge and Social Policy," as it appears on page 175 of Merton, [1975] 1976.)

As you see, this note anticipates misinterpretations of my having attributed the theorem to W.I. alone. Having been immersed all those many years in the sociology of science, I had inevitably become aware of the frequent pattern of swift mis-imputations

---

[23] Early scholarly studies of the reward system of science include Gaston (1971), Hagstrom (1974), and Zuckerman (1977); for an analytical overview, see Zuckerman (1988:520-26). Drawing extensively upon sociological sources, the popular volume by the science journalists, Broad and Wade (1983), soon catalyzed the attention paid by the mass media to deviant behavior in science.

[24] On re-reading, I find the term "*anticipatory*" rather redundant.

of ideological or other bias. Hence, my evidently unavailing effort to counter in advance the charge that my attribution simply expressed (witting or unwitting) "sexism" or, in a parallel construction, inverted "ageism." Or that the attribution was simply another instance of the Matthew effect.[25]

I should pause to report that I erred in writing that "the Thomas Theorem appears just once in the corpus of W.I. Thomas's writings." The leading authority on that corpus, Edmund H. Volkart, wrote me recently to say that he had independently made the same erroneous claim. (A comparatively rare specimen of independent simultaneous error in contrast to the many known cases of independent simultaneous discovery.) Ed Volkart had learned from our longtime mutual friend, Eleanor Isbell — for so many years, the indispensable stalwart of the Social Science Research Council — that W.I. did put the theorem into print once again. This, in his essay, "The Relation of Research to the Social Process," which appeared in a symposium by The Brookings Institution in 1931 under the title, ESSAYS ON RESEARCH IN THE SOCIAL SCIENCES.[26]

Upon examining that essay by W.I., I see that he largely reiterates the original ¶ from THE CHILD IN AMERICA in which the theorem appears, clearly making no effort to elucidate or develop it further. Still, the fact, and it is truly a fact whatever the radical subjectivists might say, that the crucial sentence [re-] appears in an essay by W.I. [alone] would seem to provide publicly accessible evidence that he knew it to be his and his alone.

Speaking of reiterations in print, I would have you turn the page to Exhibit 5. This, as you will observe at once, is another wouldbe prophylactic note that largely repeats the one published a half-dozen years before. It appears in a revised introduction to "The Self-Fulfilling Prophecy," as it appears on page 248 of Merton [1948] 1982.

Exhibit 5 *[Which reports but does not document the fact that Dorothy Thomas herself had confirmed that she had nothing to do with the concept of "defining the situation"]*

> **What we have been describing as the Thomas Theorem appears on page 572 of the book he wrote with Dorothy Swaine Thomas in 1928: *The Child in America* (New York: Knopf). I ascribe the theorem to W.I. Thomas alone rather than to the Thomases jointly because Dorothy, who became Dorothy Thomas Thomas when they were married eight years after that book appeared, confirmed that the consequential sentence and the paragraph in which it was encased were written by him. Thus, nothing in this attribution smacks of "the Matthew Effect," which operates in cases of collaboration between scholars of decidedly unequal reputation to ascribe all credit to the eminent scholar and little or none to the collaborator(s)—supplementary note, 1982.

---

[25] In retrospect, I note here the pronounced but still undeveloped effort to avoid conflating the "partial ascription *phenomenon*" and possible hypothetical *explanations* of the phenomenon in terms of sexism, ageism, or, more generally, the Matthew effect. I trust that this will be clarified in the final section of this paper which examines the sociological and methodological import of both the phenomenon and its explanation.

[26] As we shall see, Thomas emphatically quoted the theorem a third and last time in Blumer (1939:85) but did not elect to apply or develop it further. That introduces a puzzle for future exploration. What are we to make of W.I.'s own sparse attention to the specific theorem in his ample writings on the governing concept of "definition of the situation"? The very question evokes Sherlock Holmes's observation on the methodological significance of the absent: "the curious incident of the dog in the night-time; the dog did not bark." (For the imperishable original, see Arthur Conan Doyle, [1894] 1953: 347; in perhaps more immediately relevant context, the methodological fragment reproduced in *Social Science Quotations* [Sills & Merton 1991:52]).

The reason for the largely reiterated footnote is by now surely clear to you as it had become to me. It was plain that a then-and-there explanation was needed whenever one attributed the theorem to W.I. alone. Else, some were bound to conclude that Dorothy was being robbed of this part of her ample intellectual contributions. This variant of the note no longer alludes to possible imputations of gender or age bias. Instead, having set forth the grounds for the attribution, it goes on to inform, or remind, readers that the collaborators had married — on 7 February, 1935 when he was 71 and she, 34 —and that Dorothy had been a Thomas before she married another Thomas.

That allusion to the post-marital "Dorothy Thomas Thomas" must seem altogether irrelevant to the subject in hand.[27] I agree. It is there only as an echo of Dorothy's letter to me in which she describes her role in the writing of "The Children [sic] in America" and reports that "The concept of 'defining the situation' was strictly W.I.'s." But readers of those prophylactic footnotes could not surmise all that. Would that I had been able to publish in full Dorothy's charming letter to me and my reply to her. Then the story would have been writ large and plain.

But if I could not intrude that correspondence in my latter-day articles referring to the Thomas Theorem, I can surely include it here.[28]

You have only to turn to the next page of this lengthening response to your own letter to David to find Dorothy's letter as Exhibit 6 and then turn to the page[s] following for Exhibit 7.

---

[27] R.S. Smith (1993: 4-5) found that three of the 40 textbooks referring to the Thomas theorem "imply she [DST] was married to W.I. Thomas" at the time it appeared in print. He notes that this was mistaken and goes on to observe: ". . . even if they were married, this begs the question of why include such information? According to *The Chicago Manual of Style* (1982), it is not scholarly practice to identify the marital status of coauthors. It is assumed that each author is a contributor in his or her own right and so making such a point is irrelevant or detracts from the purpose of citation. As Reinharz implies in the title of her article on Dorothy Swaine Thomas ("Wasn't She the Woman Married to William I.?") citing the work in this way reinforces the patriarchal practice of subsuming a wife's work under her husband's authorship." Thus led to the Reinharz article with its nicely ironic subtitle, one arrives at it only to find next to nothing there about either the personal life or the considerable worklife of DST. As this archival letter to the Skeptical Social Scientist makes plain in virtually anticipatory style, my own echoic allusion to their marriage no more exemplifies "the patriarchal practice" of subsuming "under her husband's authorship" Dorothy's virtual lifetime of pioneering work in demography (D.S. Thomas 1938, 1941; Kuznets & Thomas 1957-64) and her pioneering studies of the Japanese detention camps during World War II (D.S. Thomas & Nishimoto 1946; D.S. Thomas, Kikuchi & Sakoda 1952) than it exemplifies a tacitly "matriarchal" practice of subsuming under his wife's authorship W.I.'s virtual lifetime of work on his concept of "the definition of the situation." It is only that even meticulous scholars of Thomasiana, such as Janowitz (in Thomas 1966:xvii) and Tate (1974), unaware that DST had been "an ardent Lucy Stoner" — an American colloquialism for a married woman who insists on retaining her birthname — have assumed that Dorothy Swaine became Dorothy Swaine Thomas only after marriage.

[28] Though persuaded then as now that discursive footnotes providing correlatives and contexts serve a useful function, I hadn't the temerity to include Dorothy's letter as a rather extended footnote in papers that, unlike this one, were not focussed on the matter of attributions of the theorem to W.I. being taken as a (witting or unwitting) expression of sexism.

Columbia University
New York City, New York 10027

Dear Bob,

Many thanks for your nice letter and the copy of your paper on the Matthew Effect in Science. I have always enjoyed reading the things both you and Harriet Zuckerman have written. There is just one point in this article that puzzles me. I assume the underlinings refer to some index. If so, you apparently have me under the Swaine. I assure you I was born a Thomas and then married a Thomas who was no relation. I was an ardent Lucy Stoner and also swore I would never change my maiden name which I didn't.

In regard to The Children in America W. I. Thomas employed me as an assistant since he had been told by the Rockefeller group to get himself a statistian. The statistical portions were mine and I am sending you under seperate cover Volkart's book which makes this clear. The concept of "defining the situation" was strictly W. I.'s. With cordial regards,

Sincerely,

Dorothy

28 September 1973

Dear Dorothy,

I treasure your sentence and, unless you say no, I shall quote it on every possible occasion as a lovely piece of sociological history. The sentence:

> "I was an ardent Lucy Stoner and also swore I would never change my maiden name which I didn't."

As for the underlining that puzzled you, that is pure and, in this case, meaningless chance. I happened to xerox the version of the paper which appears in the page proofs of my forthcoming collection of papers, THE SOCIOLOGY OF SCIENC All the proper names in the book had been underlined for purposes of indexing (and I assure you that Dorothy Swaine Thomas appears in the Index as such and not as a Swaine).

During the almost forty years (!) since I first met W. I. and you, I have retained a happy image of the two of you together, in your every joint aspect. Evidently, that was more than a casual imprint.

As for the possible Matthew effect involving W. I. and you, I had only this in mind. True, you were very much the junior assistant but W. I., in his generous way, saw to it that you were identified as co-author on the title page. It is therefore of some interest that repeatedly THE CHILD IN AMERICA is cited as being by W. I. alone. Of course, that has nothing at all to do with W. I.'s concept of "defining the situation." That was a basic sociological idea for many when I was a freshman first becoming excited by this oddly-shaped field known as sociology.

Yours ever,

Bob

[But before concluding this long response to SSS, still another intervention is needed by way of context: For lengthy though it is, this now archival document nevertheless did not include an essential part of Dorothy's and my correspondence; namely, my note signaling the pertinent passage in the "Matthew Effect" paper which led to her altogether unexpected singling out of W.I.'s and her own distinctive roles in writing *The Child in America*. Here, then, is that note as the only-now interpolated

Exhibit 7A *[which, along with Exhibit 1, had evoked Dorothy's smoking-gun reply that was reproduced as Exhibit 6 in the 1988 letter to SSS]*

31 August 1973

Professor Dorothy S. Thomas
Center for Population Research
Georgetown University
Washington, D.C. 20007

Dear Dorothy:

I had hoped to see you at the meetings and that is why I hadn't written you before now. And how wise you were not to come: 98° in the shade all through the sessions.

I am flattered to have you ask for a photograph of me but I don't have one at hand of me back in the days when I was president. But I'll see if I can dig one up and will happily send it on to you.

In the meantime, I thought you might have some interest in the enclosed paper if only because of what I say about you, W.I., and <u>The Child in America,</u> *on pp. 446-7.* [Italics have been added to underscore the relevant sentence that evidently evoked the unsolicited smoking-gun reply].

Yours,
Bob

It is of prime evidentiary importance that neither this note nor the indicated passage in the accompanying copy of "The Matthew Effect" (which appears as Exhibit 1 in the letter to SSS) refers to the partial citation of *the Thomas theorem*. As can be seen, the passage refers only to the partial citation of *the book*. It then proceeds to account for this instance of the partial citation phenomenon in terms of the Matthew effect, which is said to be all the more probable since the less-known collaborator is "subject to the double jeopardy of being a woman of sociological science and still in her twenties."[29] Yet, it will be noticed that *on her own initiative*, Dorothy Thomas takes occasion to partition their distinctive contributions to the book to emphasize that as W.I.'s statistical assistant "The statistical portions were mine and . . . [t]he concept of 'defining the situation' was strictly W.I.'s." The concluding portion of this retrospective article will collate the many statements, both public and private, to the same effect by both Dorothy and W.I. But first the conclusion of the long letter of response to SSS back in 1988.]

And there you have the essential documentation. These seven Exhibits could surely be extended in my old and new Thomasian files.* But perhaps this documentation is enough to indicate that SOCIAL SCIENCE QUOTATIONS will not be perpetuating any "institutionalized sexism" by attributing the Thomas Theorem to W.I. Thomas.

Yours, truly, from an era not quite so new,

Bob
Robert K. Merton

---

[29] Readers may want to refresh their memory by glancing back at Exhibit 1.

* . . . I append a few other Exhibits which might have been incorporated in the letter proper were this being put together on a word-processor rather than an old-fashioned Selectric II typewriter.

21 May, 1981

Dear Bob:

Checking through hundreds of copy-editor's queries on my book I had occasion to check ST &SS for the Thomas Theorem. To my surprise I find no footnote to the original "If men define things as real..."

I am convinced that if you chose to present it without footnote then you were applying some rule of common knowledge that makes the footnote unnecessary - indeed, perhaps vulgar.

So - I ask, even implore - for a spelling out of the rule (as I lay choked in dusty tomes pursuing thankless searches for forgotten footnotes).

Yours,

Cynthia

Dear Cynthia:

Having a specific page reference* for the Thomas Theorem will in truth make your book quite distinctive. As you may have noticed, there are precious few cases - in fact, I don't recall many - referring to the famous sentence which do accurately pinpoint its source. This gives the impression that ST&SS may indeed have served as a conduit over the past thirty years for the Thomas Theorem. At any rate, I enclose the page reference.

I should explain that I attribute it to W.I. Thomas, rather than to both Dorothy Thomas and him because I once asked Dorothy about it. She was emphatic that both idea and formulation were entirely W.I.'s. Incidentally, she once told me also that part of the reason -- perhaps, only a very small part -- for her marrying W.I. is that it allowed her (as a Lucy Stoner) to retain both her maiden name and to take on her husband's name as well.

I write this just hours before Harriet and I take off on our much-awaited holiday in Italy and London.

With much love,

Yours,

Bob

Social Mechanisms Generating the Partial Citation Phenomenon

As indicated at the outset, this article is not primarily concerned with adjudicating claims to the origin of the Thomas theorem, and surely not with doing so on behalf of W.I. Thomas or Dorothy Swaine Thomas. Both simply took that origin for granted. We shall be examining further crucial evidence, from both a private archive and from publications, bearing on the recently disputed origin of the theorem, but our primary objective remains to understand the partial citation phenomenon and its place in the reward-system of science by analyzing this particular instance of that phenomenon as a strategic research site. The case of the Thomas theorem provides a strategic site if only because I happen to have first-hand and fine-grained archival information about the origin of the theorem, its early citations and subsequent citational history, the latter having been

usefully amplified by the Smith (1993) survey of the theorem in textbooks.[30] And though some of that archival material appears in the foregoing documentary letter to SSS, it leaves a variety of specific historical puzzles and generic sociological problems still to be specified and solved if we are to understand the specific case of partial citation and, through it, the general phenomenon. We begin with specific historical puzzles — how did it happen that the Thomas theorem was singled out for attention and how did it happen that its book source was not cited from the start? — and then attempt to account for the continuation of this pattern of citation in terms of a generic social mechanism in the cultural transmission of knowledge, namely, obliteration by incorporation.

Obliteration by Incorporation

To begin with, how did this one sentence come to be selected for incorporation in canonical knowledge from some 12,000± sentences comprising that book of 583 pages? After all, the Thomas theorem was neither the core subject nor the main theme of *The Child in America.* But if it was not central to the book, it *was* central — indeed it was a climactic formulation — for those social scientists in W.I. Thomas's invisible college[31] who for some time had been drawing upon his concept of *definition of the situation.* It crystallized a new phase of that evolving concept by adopting a pragmatic position to say much in little about the subjective component of action being truly consequential. And so members of that invisible college promptly fastened onto this new focus on consequences of definitions of the situation.

As was briefly noted in reviewing the early diffusion of the theorem, an integral member of that invisible college was the sociologist and social psychologist Kimball Young and, to the best of my knowledge, it was he who first isolated the sentence for conspicuous attention. This, it may be remembered, he did soon after publication of *The Child in America* by adopting it as an epigraph twice: the first time for Part Four of his textbook *Social Psychology* (1930: 397) and the next year for his chapter in an edited anthology, *Social Attitudes* (Young 1931:100). The first epigraph ascribes the quotation simply to "Thomas" *sans* given name or initials (just as the two other epigraphs on that same page are ascribed to [the tentatively inferred Ernest W.] Hobson and [the surely inferred

---

[30] It turns out that R.S. Smith has expanded his 1993 presentation to the Eastern Sociological Society and that this enlarged paper is scheduled for publication in *The American Sociologist* under the title, "Giving Credit Where Credit Is Due: Dorothy Swaine Thomas and the 'Thomas Theorem.'"

[31] In a felicitous stroke of terminological recoinage, Derek de Solla Price ([1963] 1986, passim; see Index) adapted Robert Boyle's seventeenth-century term "invisible college" to designate past and present informal collectives of closely interacting scientists limited to a size "that can be handled by inter-personal relationships." See also Diana Crane, *Invisible Colleges* (1972).

John] Wesley). The second book, which the dedicated Young[32] had dedicated to his master, W.I., ascribes the quotation more definitely to "W.I. Thomas." But as is commonly the case with epigraphs, neither of these gave a bibliographic reference to its source. Thus began the unpremeditated practice of quoting the Thomas sentence *sans* the full scholarly citation.

In examining its early diffusion, we also noted that the first descriptions of the sentence as "the Thomas theorem" likewise provided no bibliographical citation. And this for reasons as happenstantial as Young's having first quoted the sentence in epigraphs. The first such description of the quoted sentence as "W.I. Thomas's sociological theorem" (Merton 1938:333) was merely a passing allusion that clearly required no citation while the first detailed reference to the truncated "Thomas theorem" (Merton 1948) appeared in *The Antioch Review*, a journal for the common reader which did not look kindly on footnotes in general and on bibliographical citations in particular.[33] (The one citational footnote in this article was not to the theorem but referred to a publication that appeared while proofs were being corrected and was barely negotiated into being.) And when the article was reprinted, as it often was, the citation remained absent.

Thus it was owing to peripheral and surely unplanned circumstances that these early appearances of the theorem in print did not include the usual academic citations of its source. This chanced feature of its primary diffusion from members of the invisible college to the larger community of sociologists became serially reproduced in the course of secondary diffusion through textbooks and correlative writings. Thus there developed a special eponymous variant of the social mechanism known in the sociology of science as "obliteration by incorporation" or by the ultimate brevity, OBI, an acronym that stands for Obliteration of the source of ideas By Incorporation in currently canonical knowledge (Merton 1968: 27-28, 35-37; Garfield [1975] 1977).

This is described as a "special eponymous variant" inasmuch as OBI ordinarily involves obliteration of *both* the author(s) *and* the original source. This unplanned social mechanism consists in "users and consequently transmitters of the particular bit of knowledge [having] become so thoroughly familiar with its origins that they assume this to be true of their readers as well. Preferring not to insult their readers' knowledgeability, they no longer refer to the original.

---

32 At the time Young was seizing upon the theorem for his epigraphs, he also wanted to do a biographical piece on W.I. who emphatically refused to give him leave. Characteristically, he responded to Young's urgent request in this vigorous fashion: "I don't regard myself as important. I don't want to be noticed. I don't care whether a word appears about me in print, living or dead." Unhappily, Thomas's wish remains fulfilled: there is still no full-scale biography of this founding American sociologist. Manuscript letters by Kimball Young (30 April, 1930) and by W.I. Thomas (4 May, 1930). I am indebted to David L. Sills for making these letters available to me. Although Kimball Young's newly published oral memoir (1995) is at times fallible when unchecked by supporting documents, this deftly edited account provides much detail about the W.I. and the Dorothy Swaine Thomas sociocognitive network.

33 None of the other five articles in that June 1948 issue of *The Antioch Review* contained a citational footnote; there were five discursive footnotes all told. The next (September) issue consisted of 17 articles, with a total of six citational footnotes.

source" (Merton 1993:218-20) as is the case, for example, with such diverse knowledge-units as the theory of games, secondary analysis, revealed preference, opportunity costs, or latent structure analysis.

At the tail end of the OBI mechanism, many concepts-and-phrasings — such as charisma, stereotype, lifestyle, significant others, double-bind, and role-model among countless others — enter the vernacular, with rare if any awareness of their sources in the social sciences (Merton 1982:100-106). Obliteration by incorporation in the general culture set in long before for much-quoted dicta and concepts such as Francis Bacon's "knowledge is power" (1597), Joseph Glanvill's "climate of opinion" (1661), and John Adams's "government of laws and not of men" (1774). But plainly, in those cases where a scientific contribution has been eponymized, as with Boyle's Law, Halley's comet, Le Chatelier's principle, the Rorschach test, Gini coefficient, or Thomas theorem, only its original bibliographic source and not its author or authors becomes obliterated. I hazard the hypothesis that when the new idea is not eponymized, its source is more probably, more rapidly, and more extensively, deleted.

Thus, in his fine account of "the Chicago School of Sociology," Lester Kurtz (1984:34) in effect exemplifies both types of obliteration — of publication only and of author too — as he reports the differing fates of Thomas's uneponymized and eponymized concepts:

> The most persistent of [W.I.] Thomas's specific contributions is his emphasis on interaction and situations in the study of the subjective side of social life. His concept of the 'definition of the situation' has become one of those concepts so widely used in sociological analysis that it is often not explicitly attributed to Thomas. His situation analysis is a result of the influence of pragmatism, and much of his later work can be encapsulated in his phrase 'If men define situations as real, they are real in their consequences' (Janowitz 1966, p. xl). Much has been made of the formulation, called the 'Thomas theorem' by Merton (1968, pp. 475ff.), including efforts to link it with dramaturgical and ethnomethodological perspectives . . .[34]

To be necessarily obvious about it, when authors fail to provide a citation to the original source of a concept or quotation, this cannot directly lead their

---

[34] Along with providing apt examples of the two degrees of obliteration — complete obliteration of the source of the generic *concept* (definition of the situation) and inevitably only partial obliteration of the source of the *eponymous theorem* — this brief passage provides a singular array of well-identified patterns in the transmission of knowledge. Thus, the thoroughly knowledgeable scholar Kurtz elects to cite a secondary rather than primary source of the theorem, taking care to abide by an only slightly institutionalized norm of citation by citing that mediating source in precise detail. Degrees of obliteration in the transmission of knowledge are also exemplified as Kurtz draws upon Janowitz's observation that "much of this later work [by W.I. Thomas on what 'he called situational analysis'] was encapsulated in *his* [*n.b.*] phrase, 'If men define situations as real, they are real in their consequences,' as stated in *The Child in America*." (Janowitz 1966:xl). But then we find that authoritative scholar of the Thomas corpus, Morris Janowitz, not pausing to give a full citation indicating where the Thomas sentence is to be found in that expansive 583-page volume. And as a final irony in Kurtz's meticulous passage, we note that though he cites only a mediating source for the consequential sentence itself, he carefully cites the exact primary source of its eponym, "the Thomas theorem."

readers to that source. Such omissions make for the type of serial diffusion that merely reproduces the pattern of an uncited concept or quotation. Failure to cite a source need not, of course, result only from chance circumstances such as those at work in the early history of the Thomas theorem. It may also result from a conflict between diverse social and cognitive functions of citation. As the reward system of science evolved, paying peer respect by citing one's predecessors became essential to it, but plainly it would be highly inefficient were scholars required to specify the origins of every bit of incorporated knowledge every time it was put to use. As Kaplan (1965) and Garfield (1995) have in effect shown, the norms governing citation practice are still neither sufficiently detailed nor standardized to solve this problem of conflicting functions of citation.

At any rate, the Thomas theorem suffered a deficit rather than such excess of precise citation. This, owing to the chance of its first quotations by members of the Thomas invisible college having appeared in the form of epigraphs and eponyms that failed to signal its precise source. That omission was reproduced through later serial diffusion among authors who had themselves evidently not come upon the original source in *The Child in America*. Despite the later precise citations of the theorem by members of the Thomas invisible college (starting with the Volkart anthology of W.I. Thomas in 1951), that outcome of obliteration except for the eponym is, to judge from the Smith (1993) survey, still typical of textbooks introducing students to sociology. Obliteration by incorporation in the transmission of knowledge remains a largely intact process until subjected to exogenous historical or sociological examination.

But if these social mechanisms of OBI and serial diffusion account for the widespread failure to cite the book source of the theorem at all, they plainly do not account for this double case of the partial citation phenomenon which has W.I. Thomas being solely credited not only with the theorem but also with the book in which it appeared. Each of these types of partial citation derived from distinct though mutually reinforcing social mechanisms in the transmission of knowledge and so requires separate analysis.

Primary Group Ascription of the Theorem to W.I.

There was nothing problematical about the origin of the theorem among members of the Thomas sociocognitive network and particularly among those who at the time the theorem appeared or soon afterwards were in close touch with the central figures of that network, W.I. Thomas and Dorothy Swaine Thomas.[35] Members of the network who have entered this account as early

---

[35] Much tacit and explicit knowledge was exchanged in such networks then as now, Those networks were, of course, less numerous and less specialized back in the 1920s and 1930s when the membership of the American Sociological Society numbered some 1200, less than a tenth as many as the membership of the ASA in the 1970s and 1980s. (I am indebted to Valerie Pines of the ASA for this information.) One-time members of the Thomas networks are of course in increasingly short supply; my own relatively youthful engagement with the Thomases did not begin until W.I. came to Harvard as a visiting professor in the mid-1930s, the year I became a newmade instructor.

disseminators of the theorem — Kimball Young, Howard P. Becker, Willard Waller, and myself — had ample cause to regard the theorem simply as a memorable formulation of a new aspect of W.I.'s longstanding paradigmatic idea of definition of the situation. Which we know was also the case with Dorothy Thomas herself since, without any prompting on my part, she had volunteered as much in her smoking-gun letter (cf. Exhibit 6).

However, what was transparently obvious at the time to Thomas colleagues close-by and at-a-distance has evidently become problematic in this time of political correctitude — at least for those who define the sole ascription of the theorem to W.I. Thomas not as a matter of historical fact but simply as an expression of sexism. It may therefore be useful to collate a few more bits of evidence from both public print and private archive that bear upon this current definition of this particular situation as further prelude to an analysis of the widely diffused partial citation of the book and the theorem.

DST'S RETROSPECTIVE ON *The Child in America*

Some twenty years before Dorothy Swaine Thomas had crisply and emphatically described W.I.'s and her own distinctive contributions to the book in the smoking-gun letter, she had taken the occasion of her Presidential Address to the American Sociological Society to do so in much greater detail. An incomplete private archive yields an almost instant response to the Address that impatiently aimed to spread the word just a bit more quickly in a way typical of sociocognitive networks.

26 September 1952

Dear Dorothy:

Thinking back, I find that I'm glad to be a member of the Council. I am sure I would have seen nothing of you at the Atlantic City meetings if I hadn't been among those fortunate few who spent almost three whole days in your private suite. I've told Paul Lazarsfeld about your presidential address and if you have a spare copy of it, could you send it on for him to read so that he will not have to wait for publication?. . .

The response follows soon:

October 3, 1952

Dear Bob,

I too enjoyed the three days of Council meetings. Thanks for your kind remarks. I do not have an extra copy of the Presidential Address, but it will be published in the December issue of the Review. Under separate cover, I will send you, within a few days, a copy of a very good picture of W.I . . .

What, then, does Dorothy Thomas (1952: 665) have to say about our subject in that Address by the first woman to become president of the then ASS? Herewith, a few snippets from this autobiographical piece on the life of the mind (that still bears re-reading):

The framework of *The Child in America* was W.I. Thomas's famous situational approach . . . which defined the 'total situation' as always containing more or less of the subjective. . . It is always dangerous to try to reconstruct the separate contributions of

collaborators, but I am reasonably sure that the designation of subjective, documentary materials as the 'as-yet unmeasured' and the emphasis on 'transmuting' more and more factors 'into quantitative form' were mine and that the very positive evaluation of the behavior document *per se* was W.I. Thomas'. For when I joined the staff of the Child Development Institute at Teachers College in 1927, I was still somewhat distrustful of the subjective and the 'as-yet unmeasured' as materials for scientific investigations. I still preferred to work with the objective, defined in almost mechanistic terms and to count, measure, sample, fit curves, correlate, test for reliability, validity and the significance of quantitative differences, rather than to utilize descriptive materials or life histories, case records, and other types of personal documents. I hoped, indeed, that the series of observational studies of social behavior which I directed there and continued during the 1930's at the Yale Institute of Human Relations might yield 'data as objective as the best of those with which the statistical economists' were dealing. And although I gave verbal recognition to the value of case histories, diary records, and what I called 'merely descriptive' accounts of behavior as 'hypothesis-forming material for further studies' I made slight use of these materials, on the ground that they 'obviously [would] not yield data appropriate for statistical analysis' (D.S. Thomas 1952: 665 citing D.S. Thomas 1929: 19-30, passim).

This public avowal with its emphasis on Dorothy Swaine Thomas's commitment to 'objective' statistical analysis inevitably brings to mind her statement in the 1973 smoking-gun letter that "the statistical portions [of *The Child in America*] were mine." That specialized role was in effect reaffirmed by W.I. (who insisted on declaring his technical ignorance of statistics) when he concluded one of the only two papers in which he reproduces the theorem by stating that "Dorothy Swaine Thomas, of Yale University, is responsible for the items relating to statistical procedure in this article."

DST'S TACIT APPROVAL OF VOLKART'S 1951 ASCRIPTION TO W.I.

At almost the same time, Dorothy Thomas is providing behavioral testimony to the division of scientific labor in the book *and* to virtual ascription of the theorem to W.I. Four years after W.I.'s death in 1947, she is first among many who are troubled by the lack of access to his works "in the field of social behavior" that were out of print or had never been published (Thomas 1951:xi). She draws upon three colleagues, near and far, in her own sociocognitive network — Donald Young, Thorsten Sellin, and Herbert Blumer — to serve with her as a committee of the Social Science Research Council to oversee the collection of W.I.'s writings that was to be brought together by Edmund Volkart (Thomas 1951). Volkart of course elects to reprint the consequential final chapter of *The Child in America* (duly cited as written by the two Thomases) and observes in his introduction to it that "the importance of subjective experience to a science of behavior is still emphasized." That continuing emphasis on the subjective is manifestly being ascribed to W.I. and surely not to Dorothy Swaine Thomas for, as we know, she is just then reporting in her presidential address her (since relaxed) "distrust of the subjective" at the time the book was being

written.[36] Volkart goes on to note, as a matter of course, that "In this connection Thomas' [*n.b.*, not "the Thomases'"] discussion of the life history as a source of research material should prove especially useful to students of culture and personality." As a member of the committee supervising the volume, Dorothy Thomas evidently did not object to this reading of the chapter containing the paragraph on the value "of the highly subjective record . . . for behavior study" which culminates in the theorem. Once again, we are put in mind of her smoking-gun letter which resonates with that reading of the chapter when she writes that "the statistical portions were mine and I am sending you under seperate [sic] cover Volkart's book which makes this clear. The concept of 'defining the situation' was strictly W.I.'s."

WIT'S SMOKING-GUN ASCRIPTION OF THE THEOREM TO HIMSELF

W.I. evidently agreed. For long before, he had anticipated Dorothy Swaine Thomas's private smoking-gun letter in a public smoking-gun ascription to himself while addressing a panel of social scientists appraising Blumer's critique of *The Polish Peasant*; this, in the course of yet again stating his methodological case for "the behavior document, whether autobiography, case record, or psychoanalytic exploration."[37] In a matter-of-fact vein (here italicized for emphasis, no doubt needlessly), he remarks that "*I* quote what *I* said in this connection" and then proceeds to quote the passage from *The Child in America* we have come to know so well, the one that closes with the now symbolically historic sentence: "If men define situations as real, they are real in their consequences" (W.I. Thomas in Blumer 1939:85).

DOCUMENTARY CONFIRMATION OF THE DST AND WIT SMOKING-GUN ASCRIPTIONS

Even in the absence of these archival and published documents by both Thomases, intellectual historians would have little difficulty in ferreting out the

---

[36] I write "since relaxed distrust of the subjective" inasmuch as the presidential address concludes, with typically Thomasian candor: "On the behavioral side, I have not found it profitable to proceed as if all behavior must be or even can be 'transmuted' into quantitative terms. And whereas I still push the statistical aspect of all studies to the limit, I no longer relegate the subjective and the descriptive to secondary positions" (Thomas 1952: 669). It was that kind of candid public retrospective that elicited this fan letter drawn from my own private archive: "I salute our out-going President — this being said as a sociologist and referring therefore to the Chief Executive of the A.S.S rather than the U.S.A. The particular occasion for my drinking to your good health is the appearance, in print, of your salty, meaty and otherwise nourishing presidential address. It stands up on the printed page as it did before the collected audience. Most of us never try to make sense of the life of the mind we have led, and of the few who do try fewer still succeed. Yours was a complete success, all the more solid for being wholly unpretentious" (RKM to DST, 27 December 1952).

[37] This, it should be noted, is a virtual quotation from a comparable passage in *The Child in America* which reads: "The behavior document (case study, life-record, psychoanalytical confession. . ." (571)

highly probable authorship of the theorem. For neither before nor after publication of *The Child in America* did Dorothy Thomas make sustained use of the theorem or the more inclusive concept of definition of the situation whereas W.I. Thomas devoted much of his twentieth-century worklife to what he described as "situational analysis." In 1917 — Dorothy Swaine Thomas was then 17 and about to enter Barnard College — his influential paper on "The Persistence of Primary-group Norms in Present-day Society"[38] observes that "this defining of the situation is begun by the parents. . ." and a few years later, *The Unadjusted Girl* (Thomas 1923) is "mainly concerned with situational analysis and the definition of the situation" (Janowitz in Thomas 1966:xxvii). But rightly enough, it is his presidential address to the American Sociological Society, a year before publication of the for-us landmark book, *The Child in America,* that almost wholly anticipates the formulation of the theorem:

> A document prepared by one compensating for a feeling of inferiority or elaborating a delusion of persecution is certainly as far as possible from objective reality. On the other hand, this definition of the situation is from one standpoint quite as good as if it were true. It is a representation of the situation as appreciated by the subject, "as if" it were so, and this is for behavior study a most important phase of reality (Thomas 1927:7).

There it is: the essential idea, down to the detail of including the Hans Vaihinger ([1911] 1924) phrasing of "as if" as this appears in the canonical version of the theorem. This anticipatory version lacks only the pragmatic element of consequences made explicit and the felicitous formulation that made the theorem memorable.

In light of this cumulation of private and public evidence, it does not seem extravagant to conclude that Dorothy Thomas and W.I. Thomas were probably speaking truth about the origin of the theorem.

ZNANIECKI'S SUMMARY OF THE WIT AND FZ DIVISION OF SOCIOLOGICAL LABOR

This accumulation of evidence would also seem to bear upon the suggestion by Howard P. Becker that the theorem was "in content at least . . . probably Znaniecki's." Beyond this evidence is Znaniecki's statement to that panel of social scientists engaged in appraising Blumer's appraisal of *The Polish Peasant.* There he summarizes Thomas's and his own "previous results of comparative analysis and generalization," thus:

> Thomas had at the time already formulated several well known and original theories in social psychology and sociology, based upon an exceptionally great mass and variety of significant data carefully chosen from many different cultures; and in starting to collect materials concerning European peasants he meant to apply his theories to this new mass of data. I had published several works in general theory of culture and in epistemology which eventually proved to have some bearing, however abstract and indirect; the former

---

[38] Thus, in an article anatomizing textbooks in social pathology, C. Wright Mills (1943: 171) notes that "About the time W.I. Thomas stated the vocabulary of the situational approach, a social worker was finding it congenial and useful. In M.E. Richmond's influential *Social Diagnosis* (1917) we gain a clue as to why pathologists tend to slip past structure to focus on isolated situations. . ."

upon the data of Polish peasant culture, the latter on the method of handling them. (Blumer 1939:87,90)

Thus, typical of both, Thomas takes the occasion to focus anew on his concept of "defining the situation" in general and on his theorem in particular while Znaniecki has nary a word to say about concept or theorem. Instead, he straightforwardly distinguishes "Thomas's well known and original theories in *social psychology and sociology*" (which, of course, were centered on his idea of "definition of the situation) from his own "*theory of culture and epistemology*." In this way, Znaniecki is also being forthright for, like Dorothy Swaine Thomas, he too made no sustained use of the idea either before or after the great collaboration.[39]

So much, then, about how it was that members of the Thomas sociocognitive network ascribed the theorem solely to W.I. Given their first-hand knowledge of its origin, no alternative could possibly have occurred to them. But, as I have emphasized from the start, this article is primarily concerned with examining the Case of the Thomas Theorem in an effort to understand the generic partial-citation phenomenon, not with the specific matter of adjudicating its origin. And though early obliteration by incorporation and serial diffusion may explain the partial citation of the *theorem* by the authors of textbooks and others who had no direct access to this first-hand information, those social mechanisms cannot, of course, explain the practice of ascribing the *book* solely to W.I., since that was not a practice appearing often in the early diffusion of the theorem.

However, it may be remembered that documentation supplied in the archival letter to SSS briefly proposed that this specific case of partial citation of the book may have resulted from the Matthew effect operating as a generic social mechanism in the transmission of knowledge. That proposal warrants further theoretical and methodological scrutiny in light of the concern voiced by SSS that ascribing the theorem to W.I. was sexist and the renewed interpretation by Smith (1993) that this practice "can also be explained in terms of a structural issue — the genderization[40] of the discipline as part of the process of professionalization. By not citing Dorothy Swaine Thomas these authors help sustain a view of sociology as historically a male domain."

---

[39] In striking contrast to Thomas who, in his last, massive, work, *Primitive Behavior* (1937), draws upon the favored mode of situational analysis from its first page to its last. The very first sentence in the book announces that every aspect of culture "can best be approached in terms of *the definition of the situation*" while the index lists 28 pages which explicitly deploy that concept.

[40] The "genderization" of scientific disciplines has been described by Evelyn Fox Keller (1985) as involving the domination of the sciences by men scientists at the expense of recognition of women scientists. Keller (1991) has gone on to put her argument thus: "the exclusion of the feminine from science has pertained to a particular definition of science: science as incontrovertibly objective, universal, impersonal — and also masculine" (235).

The Partial Citation Phenomenon and The Matthew Effect

As the terms imply, *partial citation phenomenon* designates a fact while the *Matthew effect* designates a theory. There is no reasonable question that incomplete citations of authors occur but it remains to be shown whether and to what extent and under which conditions they are cases of the Matthew effect. This is not the place to attempt a further systematic explication of the effect but, as noted earlier, there has been a tendency to conflate the fact and the theory, the phenomenon and its proposed explanation.

In cases of collaboration between scholars of notably unequal reputation, the Matthew effect confers excessive credit on the better-known scholar(s) and little or none on the other collaborator(s). Thus, the biologists R.C. Lewontin and J.L. Hubby instructively describe the far larger numbers of citations accorded one of a pair of their joint papers as apparently

> a clearcut case of [the] 'Matthew Effect' . . . In 1966, Lewontin had been a professional for a dozen years and was well known among population geneticists, to whom the paper was addressed, while Hubby's career had been much shorter and was known chiefly to biochemical geneticists. As a result, population geneticists have consistently regarded Lewontin as the senior member of the team and given him undue credit for what was a completely collaborative work that would have been impossible for either of them alone. (Lewontin & Hubby 1985:16)

This report holds immediate interest for us here since in this case, as in countless others, the Matthew effect cannot be easily attributed to a difference of gender. After all, their fellow scientists know that both Lewontin and Hubby are males. The fact that partial or other forms of skewed citation most often refer to author-sets of the same gender is enough to raise the interesting theoretical question why, in the case of the Thomas theorem, failures to include Dorothy Thomas in citations of the theorem or the book have been promptly attributed to her being a woman and his being a man. Both W.I. and D.S. Thomas occupied complex status sets.[41] He was not merely another male sociologist nor she merely another female sociologist. They had many other differing statuses and distinctive social attributes. For example, the attribute of their comparative standing in the discipline and in the field of social psychology (in which Dorothy Swaine Thomas had not worked at all). At the time that one memorable sentence appeared in the coauthored *Child in America* and diffused as the Thomas theorem, W.I. was widely recognized as one of the most consequential of American sociologists. (A quick and, for historians of sociology, redundant indicator of his standing was provided by a study of the comparative amount of space devoted to founders of the discipline in historical textbooks that found him ranked first among living sociologists and sixth among the likes of Durkheim, Comte, Spencer, Ward, and Max Weber [Palmore (1962) 1971].)

---

[41] On the structural concept of status-set as the set of distinct socially defined positions occupied by individuals at a given time, see Merton (1968:434-38); for its application to the phenomena of "sex typing" and structural obstacles confronting women in American society, see Epstein (1970:86-101; 1988:101-28).

Thomas was esteemed in particular for his theoretical development and application of situational analysis. At the age of 64, just a year before publication of *The Child in America*, he had finally been elected President of the American Sociological Society (presumably because enough members had abandoned their prudish attitudes toward his alleged notorious adultery that had led to his dismissal from the University of Chicago ten years before). Along with his exalted place in the social stratification of American sociology and other statuses in his status set, such as his age, race, religion, ethnicity, university affiliation, W.I. Thomas also happened to be a man.

In contrast to W.I. Thomas's worldwide fame, Dorothy Swaine Thomas had yet to achieve her fame. And, as was noted a quarter-century ago (see Exhibit 1), she was also "subject to the double jeopardy of being a woman of sociological science and still in her twenties."

With such enormous differences in the extent of obviously age-related accomplishment and reputation between the two coauthors, why should we fasten onto the one status difference of gender to explain this case of partial citation? On what grounds should we assume that this one status determined both the amply warranted ascription of the theorem and the wholly mistaken ascription of the book to W.I. Thomas alone? To the extent that gender-, race-, age-, ethnic-, or other status-influenced ascriptions do enter into particular cases of the partial citation phenomenon that plainly involve the Matthew effect, they involve overdetermination (in the methodological, not the psychoanalytic, sense of having more determining factors than the minimum necessary to bring about the outcome). All this raises a series of theoretical and methodological questions.[42] How do we go about discovering whether and to what extent cognitively irrelevant statuses of authors and of peer ascribers make for the partial citation phenomenon? Do scientists tend to attribute the prime role in collaborative work by men and women to those of their own gender? If so, does this practice differ by gender? Does it obtain irrespective of the comparative standing of the collaborators generally and in their special fields of investigation? In short, there is still much to be done by way of systematic empirical investigation of the diverse workings of the Matthew effect in relation to such functionally irrelevant statuses.[43]

---

[42] These generic theoretical and methodological questions also hold specific personal interest. For, as Eugene Garfield (1994:13) has recently reported, my colleague Harriet Zuckerman and I have long been subjected to a pattern of mis-citation reminiscent of the Lewontin-Hubby experience with the skewed distribution of citations to their two joint papers. Papers written jointly by "Zuckerman and Merton" (1971, 1972) are often cited with the order of the authors reversed. This, of course, carries its own irony, since the author who Garfield notes "had identified, named, and harshly criticized" the Matthew effect thus becomes its dubious "beneficiary." The irony becomes all the greater in light of a statement inserted in a reprinting of the 1968 paper, "The Matthew Effect in Science": "It is now [1973] belatedly evident to me [RKM] that I drew upon the interview and other materials of the Zuckerman study to such an extent that, clearly, the paper should have appeared under joint authorship" (Merton [and Zuckerman] [1968] 1973:439).

[43] For inquiries into the workings of the Matthew effect, though without reference to this matter of gender- or other status-influenced attributions, see Stephen Cole (1970; 1992: chap. 6).

In their normative aspect, the partial citation phenomenon and Matthew effect make for injustices. They violate the basic norm of giving peer recognition of contributors to the common wealth of science and scholarship. And, as we have seen, such normative violations evoke deep-seated responses. To extend the normative problem in the case of collaboration among status unequals, the tendency toward this type of injustice is systemic. That systemic inequity derives in no small part from there seldom being public evidence of the respective parts taken by collaborators in a particular research since the standard format of the scientific paper "presents an immaculate appearance that reproduces little or nothing of the intuitive leaps, false starts, mistakes, loose ends, and happy accidents that actually cluttered up the inquiry. *The public record of science therefore fails to provide many of the source materials needed to reconstruct the actual course of scientific developments*" (Merton 1968:4; italics inserted).[44]

Absent such detailed information, fellow scientists and scholars are evidently inclined to think it "reasonable" that the more accomplished collaborator with a history of major contributions to the field — i.e., the one with the far better "track record" as it is often put — has probably originated a joint work or contributed more to it, — unless there is compelling evidence to the contrary. This, even though such a probabilistic inference of course tells us next to nothing about the particular case with certainty.

However, in the case of the Thomas theorem, the compelling evidence is there and this time it is not to the contrary.

The More, the Better? A Four-Nation Study of the Inclusion of Women in Symphony Orchestras*

JUTTA ALLMENDINGER, *Munich University*
J. RICHARD HACKMAN, *Harvard University*

Abstract

This article explores what happens when members of one identity group enter an elite institution that historically has been dominated by another. Specifically, we examine associations between the gender composition of professional symphony orchestras and several outcome measures — players' reports about orchestral functioning, the quality of members' relationships, and their own motivation and satisfaction. Analyses draw on quantitative, qualitative, and historical data collected for a comparative study of 78 symphony orchestras in four nations: the U.S., the United Kingdom, the former East Germany, and the former West Germany. Outcome measures decline as women's representation increases until the proportion of women approaches 50%. Then, the downward trend flattens or reverses for many variables. The dynamics of gender integration are found to differ (1) at low versus moderate levels of female representation, and (2) as a function of national context.

What happens as members of one identity group become an increasing presence in an organization or institution that has long been dominated by another — that is, when the history of identity group exclusivity is being altered? This question can be asked of blacks entering traditionally white organizations, and vice versa. It can be asked of Palestinians entering traditionally Israeli organizations, and vice versa. And it can be asked of women entering traditionally men's organizations, and vice versa.

* *Portions of the research reported here were financially supported by the Max Planck Institut für Bildungsforschung and by the Harvard Graduate School of Business Administration. We thank Larissa Kowal-Wolk, Erin Lehman, Rebecca Roters, and Jay Tucker for their invaluable assistance in the research on which this article is based. Helpful comments on a draft of the article were provided by Teresa Amabile, Mahzarin Banaji, Sandra Bem, Hannah Brückner, Alice Eagly, Adam Galinsky, Connie Gersick, Sue-Ellen Hershman, Rosabeth Kanter, Aage Sørensen, and Ruth Wageman. Direct correspondence to J. Richard Hackman, Department of Psychology, William James Hall, Harvard University, Cambridge, MA 02138.*

Our focus is on the movement of increasing numbers of women into professional symphony orchestras, relatively elite and traditionally male organizations whose work requires close coordination among members (Block & Neuls-Bates 1979; Lehmann 1982). As will be seen, the gender integration of professional symphony orchestras is still in its early stages — which provides a historically unique window of opportunity to examine gender recomposition processes. We address what is happening at three levels of analysis: (1) to the *individuals* involved — the old hands as well as the new entrants, (2) to the *relationships* among members, and (3) to the structures, processes, and performance of the *organization as a whole.*

Existing literature on group and organizational composition provides some clues about what to expect as the proportion of women in orchestras increases. We know, for example, that the characteristic interaction styles of women and men differ (Dion 1985; Eagly 1987; Moreland & Levine 1992; Wood & Rhodes 1992) and that gender-homogeneous groups often have "smoother" processes — i.e., less conflict, more predictability, and less member anxiety — than heterogeneous groups (Jackson 1992; Morgan & Lassiter 1992; Pfeffer 1983). Smooth processes are not necessarily advantageous, however. The gender-characteristic norms that tend to emerge in homogeneous groups can limit both the personal learning of members and their collective task performance (Martin 1985:332). Moreover, conflict prompted by diversity and moderate deviation from traditional norms can enhance group creativity — a matter of special importance to performing groups such as symphony orchestras (Hackman 1992; Hoffman 1965; Nemeth & Staw 1989).

Longitudinal research exploring the implications of these phenomena for organizations that are in the midst of demographic transition would be ideal, but such studies have not yet been done. Still, by examining life and work in organizations that vary widely in how far they have come toward relative gender balance, insight can be obtained about the dynamics and effects of such transitions. The present research addresses three questions in this regard. The first assesses the size and direction of gender composition effects; the second and third begin to explore the mechanisms by which such effects come to pass.

(1) What happens to life and work in symphony orchestras as the proportion of women increases from token levels to a near-majority? A great deal is known about gender-homogeneous social systems (especially those that are dominantly male) and about gender dynamics when women have but token representation. (For an interpretive review of research on tokenism, see Yoder 1991.) But how do individual perceptions and attitudes, player relationships, and organizational functioning change as the proportion of minority members becomes substantial?

As noted by Martin (1985) and Yoder (1991), a number of scholars have suggested that once the proportion of women increases beyond the token level, life at work should improve — at least for women, and perhaps for their male colleagues as well. Evidence for this proposition is shaky at best (Blum & Smith 1988). Few studies of gender composition in organizations have sampled female representation widely enough, or included a broad enough set of dependent variables, to reliably track what happens as an organization evolves from a state of male exclusivity to relative gender balance.

Findings from those few studies whose designs do permit inferences to be made about the effects of increased female representation provide little basis for optimism. South et al. (1982), for example, examined the full spectrum of female representation across 76 work groups of varying size in six offices of a state agency (mean percentage of women = 51%, s = .27) and found that the higher the proportion of women, the less social support and encouragement for promotion they received. Two studies assessed the effects of gender composition in universities — which, like symphony orchestras, are relatively elite institutions. Toren (1990) found that the greater the proportion of women on the faculties of Israeli universities, the lower their academic ranks relative to those of their male colleagues. Alexander and Thoits (1985) assessed the academic performance of female students who recently had entered a traditionally male institution; they found evidence for underachievement by those token females who were enrolled in dominantly male departments.

A number of studies have shown that disparities in income between numerical minorities and majorities become greater as the relative size of the minority group increases (e.g., Frisbie & Neidert 1976; Martin & Harkreader 1993). Especially informative is a longitudinal study by Pfeffer and Davis-Blake (1987) that examined the impact of changes in gender composition on the salaries of administrators at more than 800 colleges and universities. They found a monotonic decline in the salaries of both male and female administrators as the proportion of women increased from token levels to the 30-40% range. Beyond that "tipping point," however, further increases in the proportion of women made little or no difference in salaries.

In the present research, we assess whether the negative consequences for individuals that sometimes accompany the entry of women into traditionally male organizations also hold for variables at the group and organizational levels of analysis. By collecting data from male and female members of orchestras that are spread across a wide portion of the gender composition spectrum in four nations, we should be able to reliably assess both the magnitude and the direction of gender composition effects. Moreover, we can determine if there is, for variables other than salary, evidence of the tipping point identified by Pfeffer and Davis-Blake.

Research Question 1a: How strong are gender composition effects on the perceptions and experiences of orchestra members? Are composition effects stronger or weaker than those obtained for comparison variables at other levels of analysis — specifically, player gender at the individual level and nation at the contextual level?

Research Question 1b: What is the direction of gender composition effects? That is, does the proportion of women in an orchestra vary directly or inversely with measures of individual well-being, relationship quality, and organizational vitality?

Research Question 1c: At what point on the gender composition continuum, if any, is a tipping point observed — and for what measures is it found?

(2) *Do female and male members respond differently to greater female representation in orchestras?* It may be that any main effects of gender composition are due primarily to the reactions of the new entrants — or, perhaps, to those of the old hands. Or it may be that members of both groups react similarly to changes in the proportion of female players.

Females. We know that highly skewed composition, which is inevitable when nontraditional members begin to enter a formerly exclusive group or organization, presents significant personal challenges to members of the entering group. The classic empirical study documenting the difficulties that women face when they enter predominantly male organizations is Kanter (1977a). This work explored in detail the experiences of women who constituted a small but growing minority in a large male-dominated firm.

According to Kanter (1977b), three processes operate in parallel to generate the unsatisfactory experiences of minority individuals. The first is heightened *visibility*, which results in minority members receiving a disproportionate share of the attention of other system members; that, in turn, leads to their experiencing excessive pressure to perform well. The second is increased *polarization* between the majority and minority groups, which results in exaggeration of those attributes that differentiate the minority members from the majority. The third is *assimilation*, which involves distortion of minority members' characteristics to fit with majority members' preexisting generalizations about them; this makes it difficult for minority members to escape their traditional roles.[1]

In the present context, Kanter's findings suggest that any dysfunctions associated with the entry of women into symphony orchestras should initially be more pronounced for the entering females than for the veteran male players. As the number of female players increases, however, women could increasingly provide both support and reality checks for one another — thereby ameliorating some of the difficulties encountered by the "pioneer" females. Indeed, in orchestras that are relatively gender balanced, women's reports about orchestral life might well be indistinguishable from those of their male colleagues.

Males. It may be that main effects of gender composition are due as much, or more, to the perceptions and experiences of the veteran men than to those of the entering women (Blalock 1967). Life in a homogeneously male orchestra surely is not much affected by the presence of one or two women, such as a female harp player. As their numbers increase, however, women become, in Yoder's (1991) phrase, an "intrusive" presence on high-status turf that previously has been an exclusively male province.

The entry of substantial numbers of women into orchestras may raise concerns among men about their dominance of the organization and control of its operations. Moreover, the presence of a noticeable and growing group of women may increase the salience of men's own identity group and prompt concerns about women taking over jobs or resources that historically have been accessible only to them (Cockburn 1985, chap. 8; Tolbert, Simons & Oberfield 1994). Men also may worry that the high status of their profession will be compromised by the entry of women — in effect, that their professional currency will be devalued (Martin 1985; Reskin & Roos 1990; Touhey 1974). Finally, the gender-characteristic patterns of interaction that the male members are likely to have evolved may now be challenged by new ways of thinking and acting exhibited by people who are perceived to be "not like us."[2]

Both Genders. The minority processes posited by Kanter and the majority processes posited by Blalock generate contrasting predictions about what will happen as the proportion of females in traditionally male organizations increases (Jacobs 1992; Pfeffer & Davis-Blake 1987; Tolbert, Simons & Oberfield

1994). The Kanter position is that things will get better, mainly because of what the women are doing; the Blalock position is that things will get worse, mainly because of how the men are reacting.

There remains a third possibility — namely, that gender composition effects will be found for *both* female and male members. This could occur (1) because the separate processes described above for females and males are both operating (and, perhaps, reinforcing one another), or (2) because orchestras with mixed gender composition actually do operate less well — and that fact is noted and reported upon by all members regardless of gender.

The relative validity of these three alternatives — that is, that gender composition effects are due primarily to the responses of female players, to those of male players, or to those of all orchestra members — can be assessed by examining the strength and direction of any interactions that are found between individual gender and orchestra gender composition in shaping players' reports about their orchestras.

Research Question 2a: Do women and men respond differently to different gender composition levels? Or do all members react similarly as orchestras become less exclusively male?

Research Question 2b: Which gender exhibits the more pronounced change in perceptions and experiences as gender composition becomes more balanced?

(3) To what extent do gender composition effects differ as a function of national context? Specifically, do the effects of women entering traditionally male organizations differ for nations that encourage women's full participation in the work force, compared to nations that are relatively neutral to (or actively discouraging of) women's participation?

A country's policies, practices, and social structures can powerfully influence the receptivity of the workplace to women (Hofstede 1980). Indeed, Schmidt (1992:47) concluded, based on data from a comparative study of gendered labor force participation in the OECD nations, that "the large cross-country variation in labor force participation rates of men and women can, indeed, be properly appreciated only in the context of 'deep-seated institutional differences' between the countries studied."

Organization members operate simultaneously in multiple gender contexts (Martin & Harkreader 1993). Between-nation differences in receptivity to women's participation in the national work force, therefore, may affect not just the overall level of women's work force participation but also how changes in organization-level gender composition unfold.

Research Question 3: How do gender composition dynamics differ for countries that have relatively high versus relatively low rates of women's participation in the national work force?

In sum, the present research explores the main and interactive effects of the proportion of women in orchestras, individual gender, and national context in predicting (1) individual motivation and satisfaction, (2) the quality of relationships among players, and (3) their reports about how, and how well, their orchestras function. Simultaneously considering variables at the individual, organization, and contextual levels of analysis, we believe, can yield insight into

the dynamics of gender compositional effects that would escape detection in research conducted at any single level of analysis.

Research Setting

The present research draws upon data from 78 professional symphony orchestras in four nations: the U.S., the United Kingdom, the former East Germany, and the former West Germany. Symphony orchestras are defined as ensembles whose primary purpose is public performance of those orchestral works generally considered to fall within the standard symphonic repertoire, and whose members are compensated nontrivially for their services. Such orchestras have several unique features that make them advantageous for examining the research questions specified above.

SALIENCE OF COMPOSITION DYNAMICS

Gender composition dynamics are likely to be especially evident and consequential for players in symphony orchestras, for two reasons. First, the work of orchestras is done literally in concert and requires a very high level of between-member coordination. In contrast to some other types of organizations (e.g., field sales operations, or schools in which teachers have relatively autonomous responsibility for their classrooms), any change in orchestra composition will be experienced immediately and continuously by all members. Second, orchestras are highly visible and relatively elite organizations. There are many qualified applicants for each opening in a professional symphony orchestra, and musicians who do secure orchestral positions enjoy relatively high status in their profession and their communities. Therefore, any change in orchestra demography is likely to be both salient and significant for all members.

ORCHESTRA TASK AND MEMBER TALENT

Variation associated with both organizational tasks and member talent is relatively low across both orchestras and nations. The core task of symphony orchestras is both well-defined and similar across nations. Although there are indeed large cultural and contextual differences among nations, symphony orchestras around the world play largely the same repertoire with roughly the same number and mix of players.[3] Thus, by defining the domain of the research to include *only* orchestras that perform the standard symphonic repertoire, most task-based variance is automatically controlled.

Use of professional symphony orchestras as the research setting also automatically controls a great deal of variation in member talent. Because there are far more talented musicians looking for work than there are open positions, most orchestras are staffed with fully qualified players. By studying symphony orchestras, then, it is possible to avoid the problem, common to comparative organizational research, that differences in organizational tasks or in the mean skill levels of organization members are confounded with organization-level variables or with the properties of national contexts.

RATES OF WOMEN'S PARTICIPATION

There is substantial variation both within and between nations in orchestra gender composition. This makes it possible to examine compositional main effects across a relatively large portion of the gender composition spectrum as well as to detect any interactions between orchestra composition and national context that shape the perceptions and experiences of orchestra members.

Although women historically have been active in music as teachers, singers, and amateur performers (Edwards 1991), it is only in recent decades that they have become accepted as full members of professional symphony orchestras. In the U.S., for example, it was not until the mid-1950s that women began to be accepted into major orchestras in more than token numbers; in the two German nations, that did not occur until the 1980s (Allmendinger & Hackman 1993a). As recently as the early 1990s, there still were relatively few female players in professional symphony orchestras, as is evident in the left panel of Figure 1. Of the 78 orchestras in our sample, only eight employ women and men in roughly equal numbers; in more than half of the orchestras, fewer than 25% of the players are female. Nonetheless, the range of female representation in the sample as a whole (2% to 59%, median = 21%) is satisfactory for our research purposes.

The four countries in our sample differ substantially in women's work force participation. Data from the International Labor Organization show that the proportion of working women in 1989 (when we drew our sample of orchestras) ranged from around 40% in West Germany and the United Kingdom to 45% in the U.S. and 50% in East Germany. Since 1960, women's workforce participation has increased in all four nations, most sharply in the U.S. (a gain of 13%), moderately in the U.K. and East Germany (gains of 8% and 6% respectively), and least in West Germany (a 3% gain).

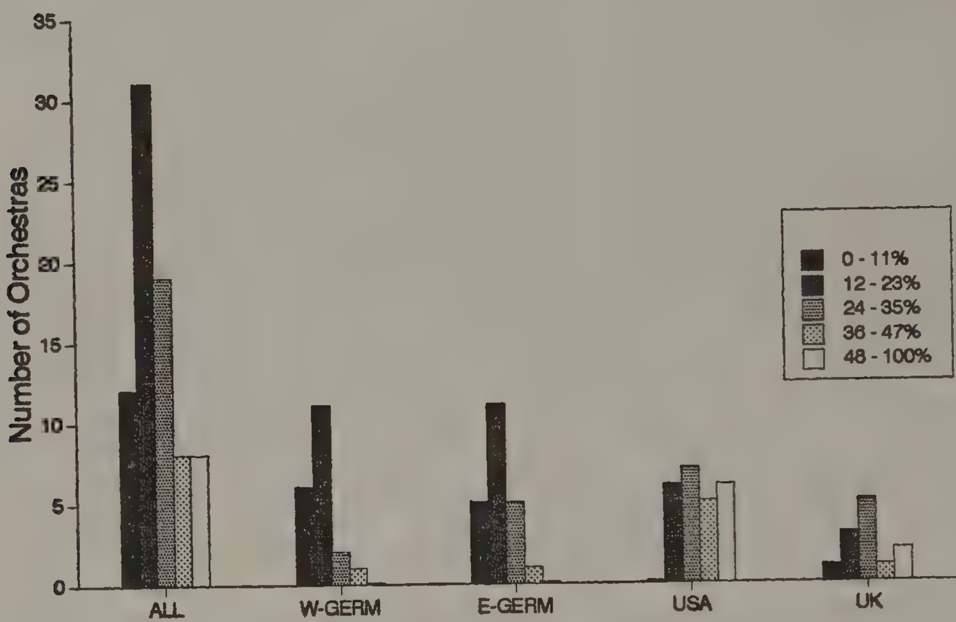
The distribution of women's representation in orchestras in each of the four countries is shown in Figure 1. The U.S. has the highest proportion of women (median = 36%), which is the lower bound of Kanter's (1977b) "low balanced" category.[4] Next comes the United Kingdom, which, with a median of 30% women, falls into Kanter's "high tilted" category. Finally, the median proportion of women in both West and East Germany is 16%, placing both of these nations in her "low tilted" category.

There are many differences among the nations in our sample, of which rates of women's participation in the work force is but one. Any attributions about the reasons for empirical findings involving differences among nations must therefore be made cautiously and conservatively. We will see, nonetheless, that differences in national context do play a significant role in how recomposition processes are unfolding in symphony orchestras in the four nations studied.

Method

This research draws upon archival, observational, interview, and survey data collected for a four-nation comparative study of leadership and mobility in symphony orchestras. We present here only those aspects of the methodology that are germane to present purposes; for a detailed description of project methods, see Allmendinger et al. (1993).

FIGURE 1: Women's Representation in Orchestras in 1990



SELECTION OF ORCHESTRAS

Professional symphony orchestras in all four countries announce all vacancies for players in union or government publications. It therefore was possible to enumerate the population of symphony orchestras in each country by listing all orchestras that announced at least one open player position between 1985 and 1989. We obtained 1989 budgets for each of these orchestras from industry, government, and trade union reports and used the distribution of salary budgets to select approximately equal numbers of relatively affluent and widely known "major" orchestras and generally smaller, more regionally oriented "minor" orchestras.

Major orchestras were randomly drawn from the top decile (or, in the United Kingdom, which had fewer orchestras, quintile) of the distribution; minor orchestras were randomly drawn from each of the remaining deciles (or quintiles) until a sample of about 20 orchestras from each country was obtained.[5] Of the 81 orchestras invited to participate, 78 agreed (96%) (the exceptions were one minor orchestra in the U.S. and one major and one minor orchestra in the United Kingdom).

SOURCES OF DATA

Data were collected during 1990 and 1991. We summarize below procedures and instruments that were common across orchestras in all four countries; special procedures that were required for data collection in East Germany are described by Allmendinger and Hackman (1992).

Four types of data were obtained for each orchestra: archival information, interviews, observations, and player surveys. Archival information includes data in the public domain (such as published histories and newspaper or magazine articles) and information obtained from an orchestra's files (such as concert programs, rosters of players and managers, financial data, and attendance figures). After reviewing published information about an orchestra, one or more project researchers visited it to conduct interviews, observe the orchestra, and collect data from the orchestra's files.

We also sought permission from orchestra management (and, when appropriate, from the players' orchestra committee) to administer a questionnaire to a sample of players. Surveys were anonymous, although they did identify the respondent's orchestra, section, and status as a principal or as a tutti player. They usually were distributed by mail (and always with a preaddressed and stamped return envelope) to a stratified random sample of 15 players in each orchestra: two first violins, two second violins, one viola, one cello, one bass, two woodwinds, two brass, one percussion, and three principal players (one each from the strings, woodwinds, and brass/percussion). After the first round of surveys had been returned, additional surveys were sent to most orchestras. The same sampling plan was used in the second round, except that women were deliberately oversampled to obtain enough responses from female players to permit comparative analyses between the responses of men and those of women.

Six participating orchestras chose not to have surveys distributed to their players: four in West Germany and two in the U.S. The sample for the main analyses reported in this article is 72 orchestras and 992 respondents. The number of orchestras, number of respondents, and survey response rates for each country are as follows. East Germany: 22 orchestras, 357 respondents (59%); West Germany: 16 orchestras, 186 respondents (45%); U.S.: 22 orchestras, 290 respondents (52%); United Kingdom: 12 orchestras, 159 respondents (51%).

SURVEY MEASURES

The player survey consisted of 87 items distributed across five domains. Originally drafted in English, the survey was translated into German (and partially back-translated) by bilingual members of the research team. Sixteen composite measures were derived, based on the *a priori* framework used in constructing the survey supplemented by principal component analyses and inspection of item means, standard deviations, and interitem correlations. Six single items of special interest also were retained, resulting in a total of 22 measures. All measures range from 1 (low) to 7 (high) except for those assessing the behavior of the music director, which range from 1 to 5.

Means, standard deviations, and internal consistency reliabilities (assessed using Chronbach's alpha) for all measures are provided in Table 1; descriptions of the measures are provided in the Appendix. Means and standard deviations are satisfactory, although internal work motivation approaches the scale ceiling. Internal consistency reliabilities range from .58 to .92 (median = .76). Two measures have marginal reliabilities: satisfaction with work relationships (.58) and adequacy of resources (.59).

Discriminant validities of the measures were assessed by comparing the average intercorrelation among items that comprise a given composite score with those items in the same section of the survey that do *not* contribute to that score ("off-diagonal" correlations). The median within-composite correlation is .46, compared to a median off-diagonal correlation of .24, which is satisfactory. Three measures, however, do have relatively weak discriminant validities: integrity as an ensemble, music director organizational initiatives, and music director coaching.

Finally, within-composite correlations, off-diagonal correlations, and intercorrelations among the 16 composite measures were compared across countries. Patterns of intercorrelations were found to be quite similar across nations, which provides reassurance about the comparability of players' responses to the English and German versions of the survey and permits use of the same composite scores for all countries. (For details, see Allmendinger et al. 1993).

ANALYTIC STRATEGY

The primary data analysis was accomplished using the SAS General Linear Models program. Each dependent variable was predicted from gender, proportion of women, country, and all interactions among these factors. A hierarchical model was used, in which gender (the design factor at the individual level of analysis) was entered first, followed in turn by proportion of women (the organizational level), country (the contextual level), and all two- and three-way interactions among these factors. To account for orchestra-specific variance, the model also included, as the last term, orchestra (a random effect) nested within standing (i.e., major versus minor orchestras).

Because the proportion of women and men in a given orchestra who returned surveys did not match the actual proportion of female and male members of that orchestra, weights were applied to the data from female respondents in each orchestra so that their contributions to orchestra-level means corresponded to their actual representation in that orchestra. Also, the uneven distribution of orchestras across design factors made it impossible to use least-square procedures to estimate some cell means. Therefore, means reported in this article were computed by first averaging the responses of all orchestra members and then averaging these orchestra-level means across the design factors of interest.

[a] Number of responses ranges from 886 to 924.

Results

Findings are presented separately for each of the three research questions set forth in the introduction to this article. First we examine the size and direction of gender composition main effects; then we examine how gender composition dynamics differ (1) for female and male orchestra members, and (2) as a function of national context.

GENDER COMPOSITION

Table 2 shows the size and statistical reliability of all main effects and two-way interactions for each of the five groups of dependent variables: perceived organizational features, music director behaviors, orchestral processes, overall player motivation and satisfaction, and player satisfaction with specific aspects of their work lives.

Effect Sizes

Gender composition is significantly related to 19 of the 22 dependent measures, most strongly with measures of perceived organizational features and least strongly with assessments of music director behavior. Of the two comparison variables, country and respondent gender, the former also is strongly related to the dependent measures (21 of 22 associations significant), but the latter is not (only 5 associations significant).

The numerous and often substantial main effects for country are the subject of a forthcoming report and therefore not discussed here. Our present interest, addressed in a subsequent section, is in *interactions* involving nation — i.e., how national context alters gender composition dynamics.

The findings regarding individual gender, on the other hand, merit close inspection. Whether as a main effect or in interaction with gender composition or with country, individual gender controls little variation in our measures. Across all dependent variables, the median proportion of variance controlled by gender and its interactions is less than 1% (compared to a median of 5% for both proportion of women and country), even though gender was entered as the first term in the hierarchical data analysis model.

It is, perhaps, not surprising that there are few significant gender effects for the measures of organizational features. It is, after all, the same organization that men and women are describing, so the absence of strong gender effects is reasonable. The only statistically reliable gender effects for these measures are that men view their orchestras as better structured and as having greater integrity as ensembles than do women (F ratios of 7.1 and 22.3 respectively, $p < .01$ for both variables).

It is noteworthy, on the other hand, that there are few significant differences in how women and men describe the behavior of orchestra leaders, internal orchestra processes, and their own motivation and satisfaction. The only significant effects are that (1) women view the music director as more active in coaching players and in doing organizational work than do men ($F = 5.8$, $p < .05$ for coaching; $F = 6.0$, $p < .01$ for organizational initiatives), (2) women are more optimistic than men about how their orchestras are doing financially ($F = 23.4$,

TABLE 2: Size of Effects of Gender, Proportion of Women, and Country[a]

	Gender		Proportion of Women		Country		Gender by Proportion		Gender by Country		Proportion by Country	
	Sig.	%†	Sig.	%	Sig.	%	Sig.	%	Sig.	%	Sig.	%
Organizational features (6 measures)	2/6	0	6/6	8	6/6	4	5/6	1	1/6	0	6/6	4
Music director behavior (4 measures)	1/4	0	1/4	1	4/4	6	1/4	0	0/4	0	4/4	4

Satisfaction with specific organizational features (5 measures)	0/5	0	5/5	2	4/5	6	1/5	0	0/5	0	3/5	2

[a] Significant three-way interactions were obtained for 2 of the 22 variables. These interactions control less than 2% of the dependent variable variance, and neither is of substantive interest. They are not discussed further.

* The number of measures for which the effect is significant at $p = .01$.

† The mean percentage of the total variation of scale scores that is controlled by the effect.

$p < .01$), and (3) men are more involved with their work (and are happier about their opportunities for personal and professional growth) than are women ($F = 40.3$, $p < .01$ for job involvement; $F = 5.4$, $p < .05$ for growth satisfaction). Other than these differences, the perceptions and experiences of male and female players within a given orchestra are, on the whole, quite similar.

Direction of Effects

Means for all dependent measures, arranged by proportion of women, are presented in Table 3. Almost all the dependent measures decline significantly as the proportion of women in an orchestra increases from token to more substantial levels. However, 10 of the 19 significant effects exhibit a statistically significant reversal of the decline at some point on the gender composition spectrum (see the *F* ratios for the quadratic component in the far right column of the table).

* $p < .01$ ** $p < .001$

All six measures of members' perceptions of their orchestras' organizational features show a significant decline as the proportion of women increases. The decline is monotonic for four of the six measures; for the other two (organizational structure and adequacy of resources) there is an initial decline followed by a significant upturn as the proportion of women becomes larger.

Reports about the behavior of the music director are generally unaffected by organizational gender composition. The measures of orchestral processes, however, are strongly and significantly related to the proportion of women in the orchestra. All four of these measures exhibit an initial decline followed by an upturn.

Finally, all measures of player satisfaction and motivation are significantly associated with gender composition, and all but two exhibit the now-familiar pattern: an initial decline followed by an upturn. The two exceptions are job involvement (which exhibits a monotonic decline) and internal work motivation (which shows no interpretable pattern).

To show the consistency of the emergent pattern across domains of dependent measures, we present in Figure 2 the means for six representative measures — two organizational features (integrity as an ensemble and organizational structure), two organizational processes (quality of interpersonal relationships and organizational stability), and two attitudinal measures (job involvement and satisfaction with job security).

Where the Variance Lives

Far more variation in our measures was found to be controlled by contextual and organizational factors than by gender assessed as an individual-level attribute. That finding is consistent with the increasing recognition of the importance of social and structural factors in explaining even those male-female differences that may initially appear to be native (Eagly 1987; Faludi 1991). Still, the nonexperimental character of our research design requires that special care be taken to ensure that the direction of our findings cannot be explained by other variables that covary with orchestra gender composition. In particular, three rival explanations must be considered: respondent age and experience, respondent instrument, and orchestra standing.[6]

Age and Experience. On average, women players in professional symphonies have served in their orchestras for substantially fewer years than have their male colleagues (means of 11 and 16 years, respectively) and they are, on the whole, considerably younger than their male colleagues. It is commonly found that older employees with more years of organizational experience are more satisfied with their work lives than are their younger colleagues (e.g., Hackman & Oldham 1976). We find the same phenomenon. Players in our sample over age 40 were significantly more satisfied than their younger colleagues on six of the eight measures of motivation and satisfaction. (The exceptions were satisfaction with job security and with pay.) This finding raises the possibility that the effects we are attributing to gender composition actually reflect the fact that orchestras with larger numbers of women are also, on the whole, younger orchestras. We tested this possibility by examining the relationship between gender composition and the six representative measures in Figure 2 separately for younger and older players. The findings, shown in Figure 3, replicate for

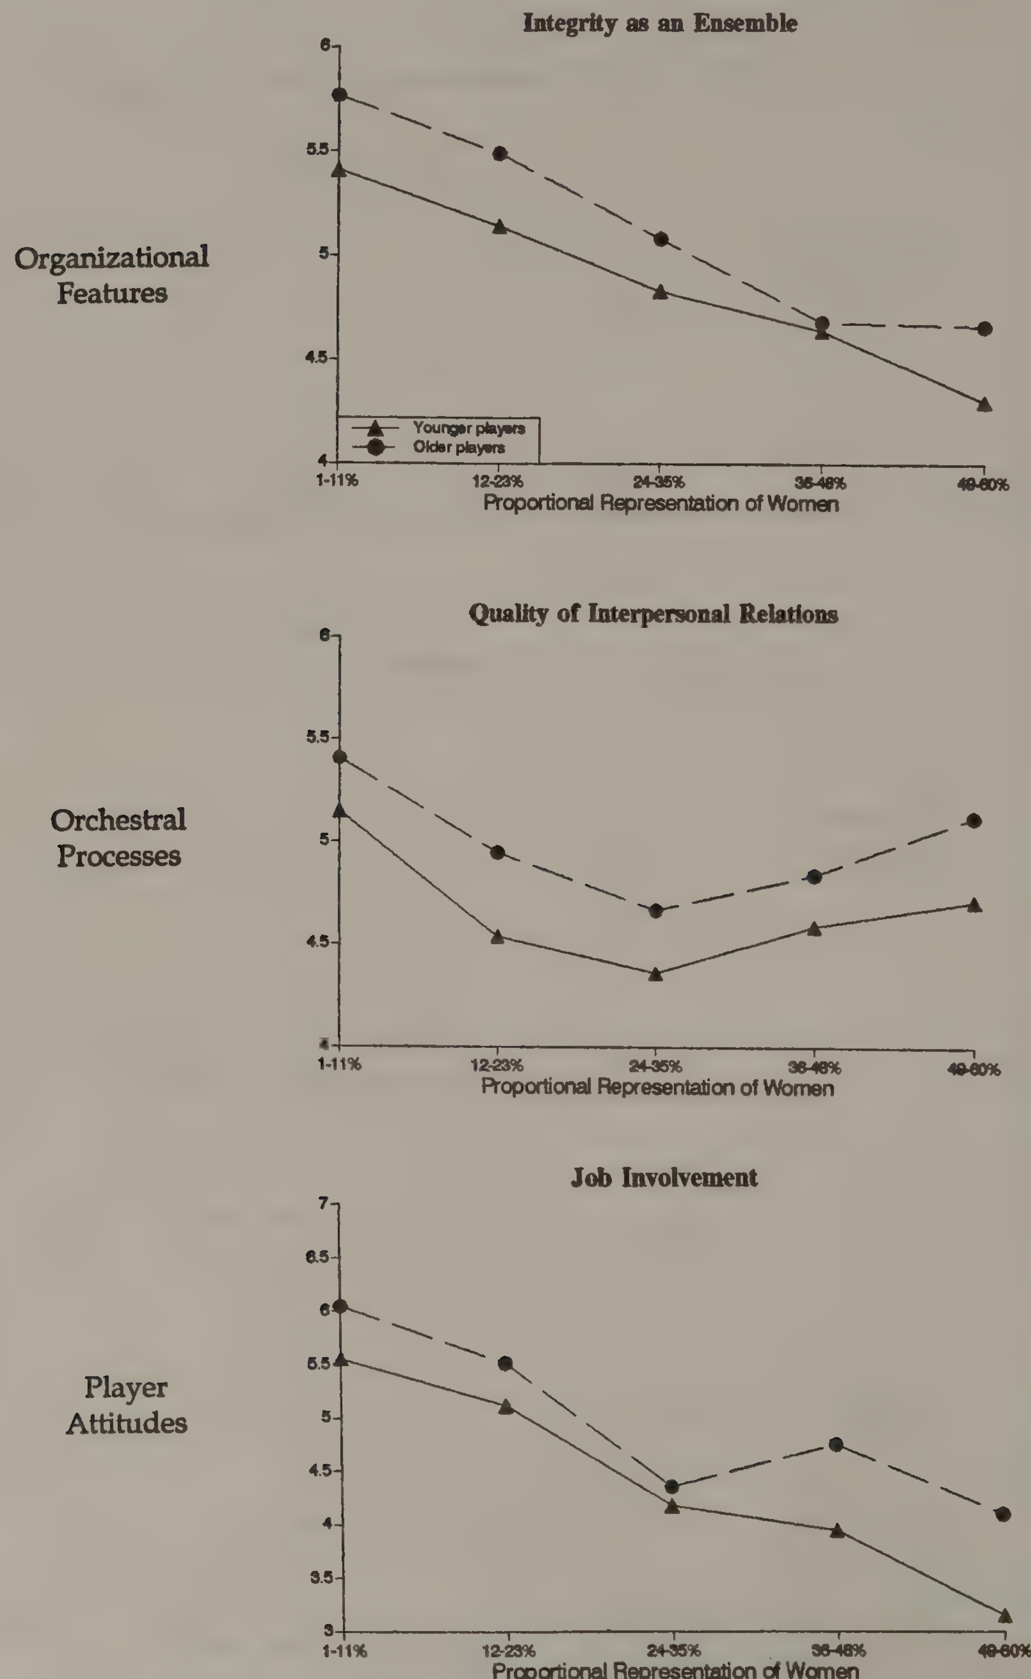

FIGURE 3: Proportion Effects for Younger vs. Older Players (Continued)

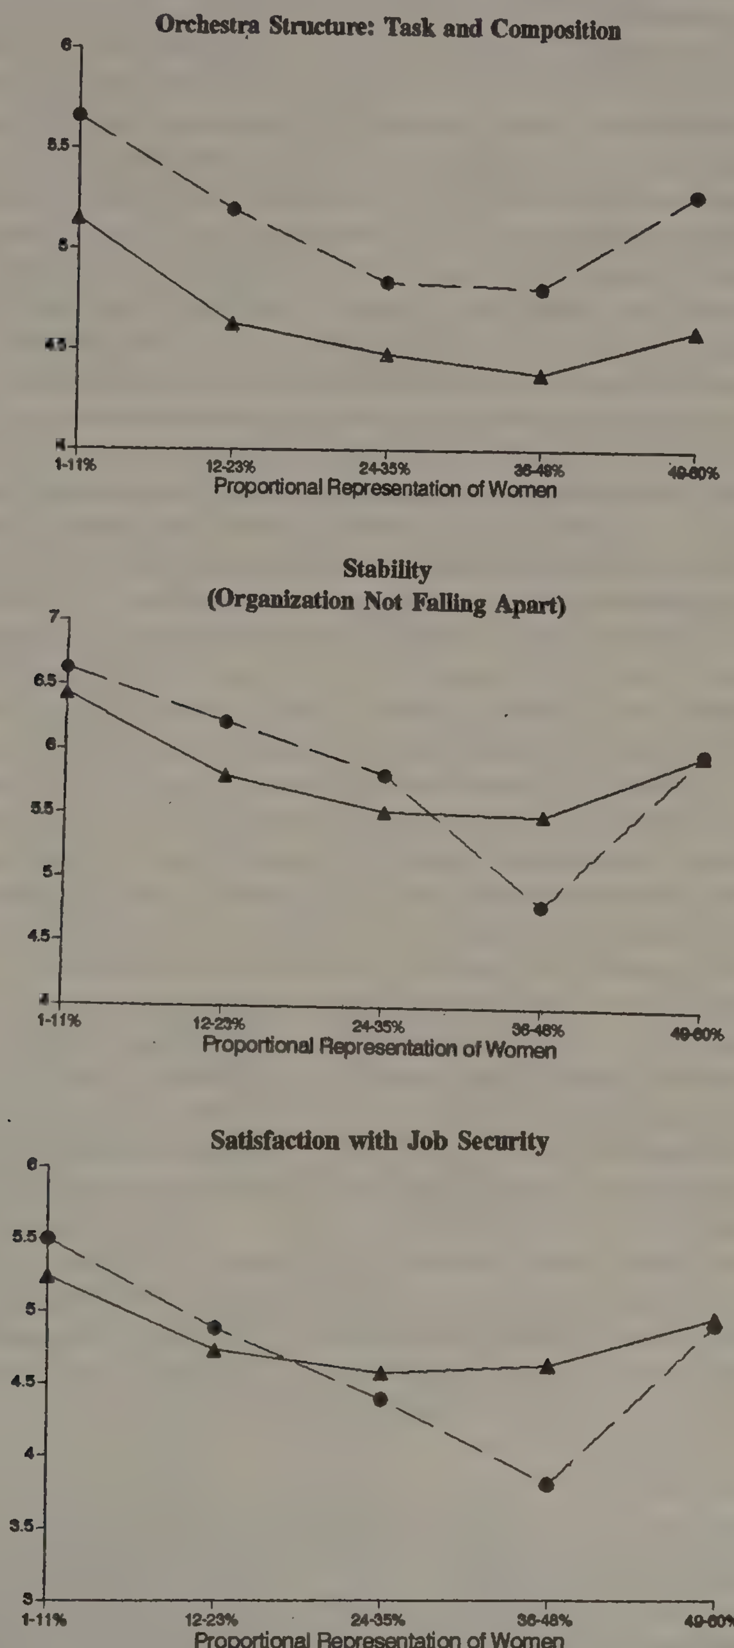
Organizational Features

Orchestral Processes

Player Attitudes



both age groups the previously reported results according to the proportion of women. The gender composition main effect is not an artifact of player age and experience.

Instruments. Another rival explanation derives from the sex-role typing of the instruments of the orchestra (Griswold & Chroback 1981). Women are significantly overrepresented in the first and second violins, violas, and cellos; they are underrepresented in the woodwind, percussion, bass, and brass sections (Allmendinger & Hackman 1993a). Thus, women play mainly in the largest sections and are not as prominent in orchestras as they would be if they were playing instruments for which there are fewer players per part.[7] This raises the possibility that the main effect for proportion of women is really an instrument effect — i.e., that it is due to differences between the violins, violas, and cellos on the one hand (which we will call female type instruments) and the basses, woodwinds, brass, and percussion on the other (which we will call male type instruments). Therefore, we examined the relationship between the proportion of women and our six representative measures separately for individuals who play female-type and male-type instruments. The findings, shown in Figure 4, once again replicate the main effect findings for gender composition. The proportion effect is not an artifact of instrument type.

Standing. When women enter a profession previously dominated by males, they usually appear initially in lower status organizations. Lie and O'Leary (1990) show this to be true for the academic profession; we find it as well for symphony orchestras. In each of the four countries of our sample (and especially in the U.S.), there is a significantly higher proportion of women in smaller, less affluent, and less prestigious minor orchestras than there is in relatively larger, richer, and more prestigious major orchestras. (The proportions of women in minor and major orchestras in each country are, respectively: West Germany, 20% versus 13%; East Germany, 22% versus 13%; United Kingdom, 38% versus 26%, and U.S., 52% versus 24%.) It is possible, therefore, that obtained main effects for gender composition are actually reflecting orchestra standing — specifically, that minor orchestras have both a higher proportion of women and lower scores on the dependent measures than do major orchestras. To test this possibility, we examined the relationship between proportion of women and our representative measures separately for major and minor orchestras. As seen in Figure 5, *major* orchestras show the more pronounced drop on our dependent measures; it is the relatively less well-off minor orchestras that are mostly responsible for the upturn that occurs for many variables when the proportion of women approaches 50%. Although unanticipated, this finding is precisely what would be expected from the research literature on gender segregation (e.g., Bielby & Baron 1986; Reskin & Roos 1990).

Summary

The findings reported in Table 3 — namely, that almost all measures of perceived organizational features, orchestral processes, and player motivation and satisfaction show an initial decline as the proportion of women in an orchestra increases — are strong and apparently stable. For many measures, this downward trend flattens or reverses when the proportion of women approaches

50%, yielding curves that are remarkably similar to those reported by Pfeffer and Davis-Blake (1987) for the relationship between organizational gender composition and salaries (compare our Figure 2 to their Figures 1 and 2, p. 15). This upturn appears to be driven mainly by the reports of players in *minor* orchestras, about which we will have more to say later.

All our dependent variables are based on self-reports by orchestra players. That presents no interpretative problem for the measures of player motivation, satisfaction, and relationship quality; for those measures, it is the players' own states and experiences that they are reporting. For the measures of organizational features, however, interpretations must be more cautious, since players' affective states may distort their perceptions of the properties of their organizations. It is instructive, therefore, to examine the relationship between gender composition and the organizational features of orchestras using data that are independent of players' perceptions. Project researchers independently assessed several organizational properties while on site at each orchestra, using a structured observational guide. The means of the researchers' assessments of two organizational features — integrity as an ensemble and orchestra structure — were computed for orchestras in the top, middle, and bottom thirds of the gender composition distribution. For integrity as an ensemble, the means (from lowest to highest proportion of women) are 5.27, 5.06, and 4.00 ($F = 9.74$, $p < .01$); for orchestra structure, the means are 5.27, 5.11, and 4.75 ($F = 1.8$, n.s.). This pattern matches that obtained using members' survey descriptions of the features of their orchestras.

We turn next to results for our second and third research questions, which explore the interactions between orchestra gender composition and (1) the gender of individual respondents, and (2) orchestras' national contexts. These findings should help identify and illuminate the mechanisms that give rise to the main effects reported above.

COMPOSITION-GENDER INTERACTIONS

The main effects reported thus far describe the combined responses of female and male players. Yet organizational gender composition may shape experiences, perceptions, and attitudes of the new entrants, women, more strongly than those of the old hands, men — or vice versa. This possibility can be tested by examining the interaction between respondent gender and orchestra gender composition. If the gender composition does affect women more than men, then (1) there should be significant gender-by-composition interactions for many of our dependent measures, and (2) the slope of the means across the gender composition spectrum should be greater for women than for men.

Table 4 shows that the first condition is met but that the second is not. Ten significant gender-by-composition interactions were obtained, but for all of them it is *men* who respond more strongly to changes in organizational gender composition. Moreover, the standing of the two genders on all dependent measures reverses between token and relatively balanced gender composition; men's reports are more favorable when there are few female players, whereas women's reports are more favorable when there are many. The typical pattern

FIGURE 4: Proportion Effects for "Male" vs. "Female" Instruments

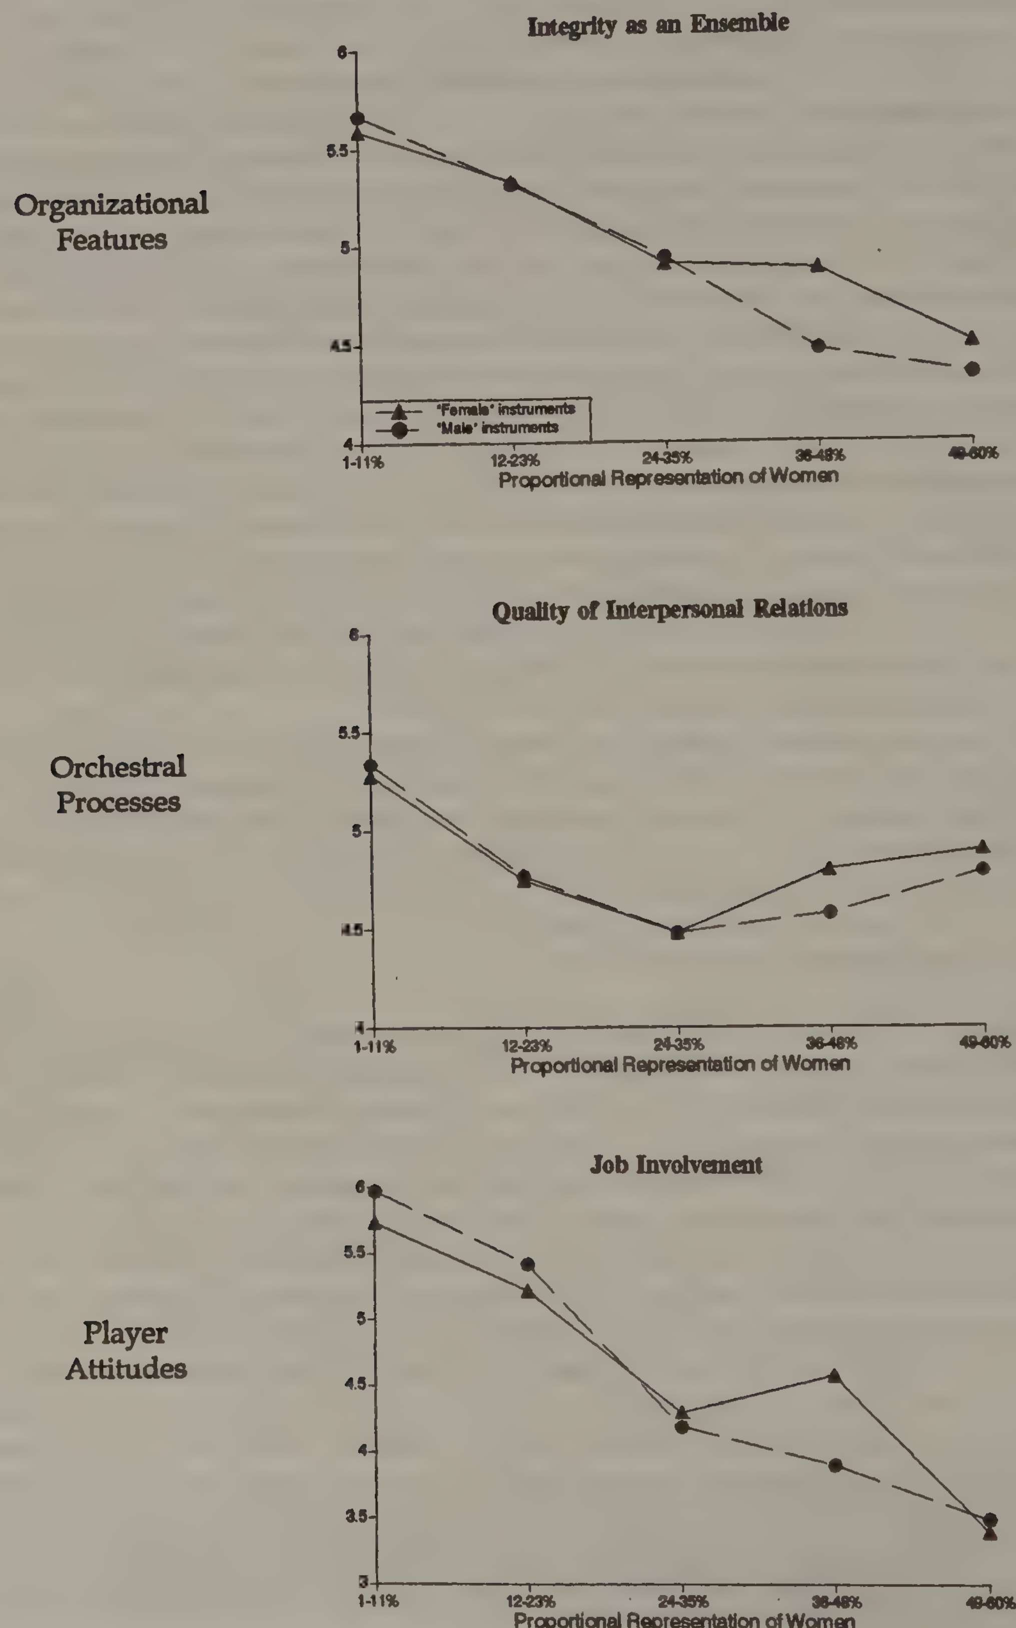


FIGURE 4: Proportion Effects for "Male" vs. "Female" Instruments

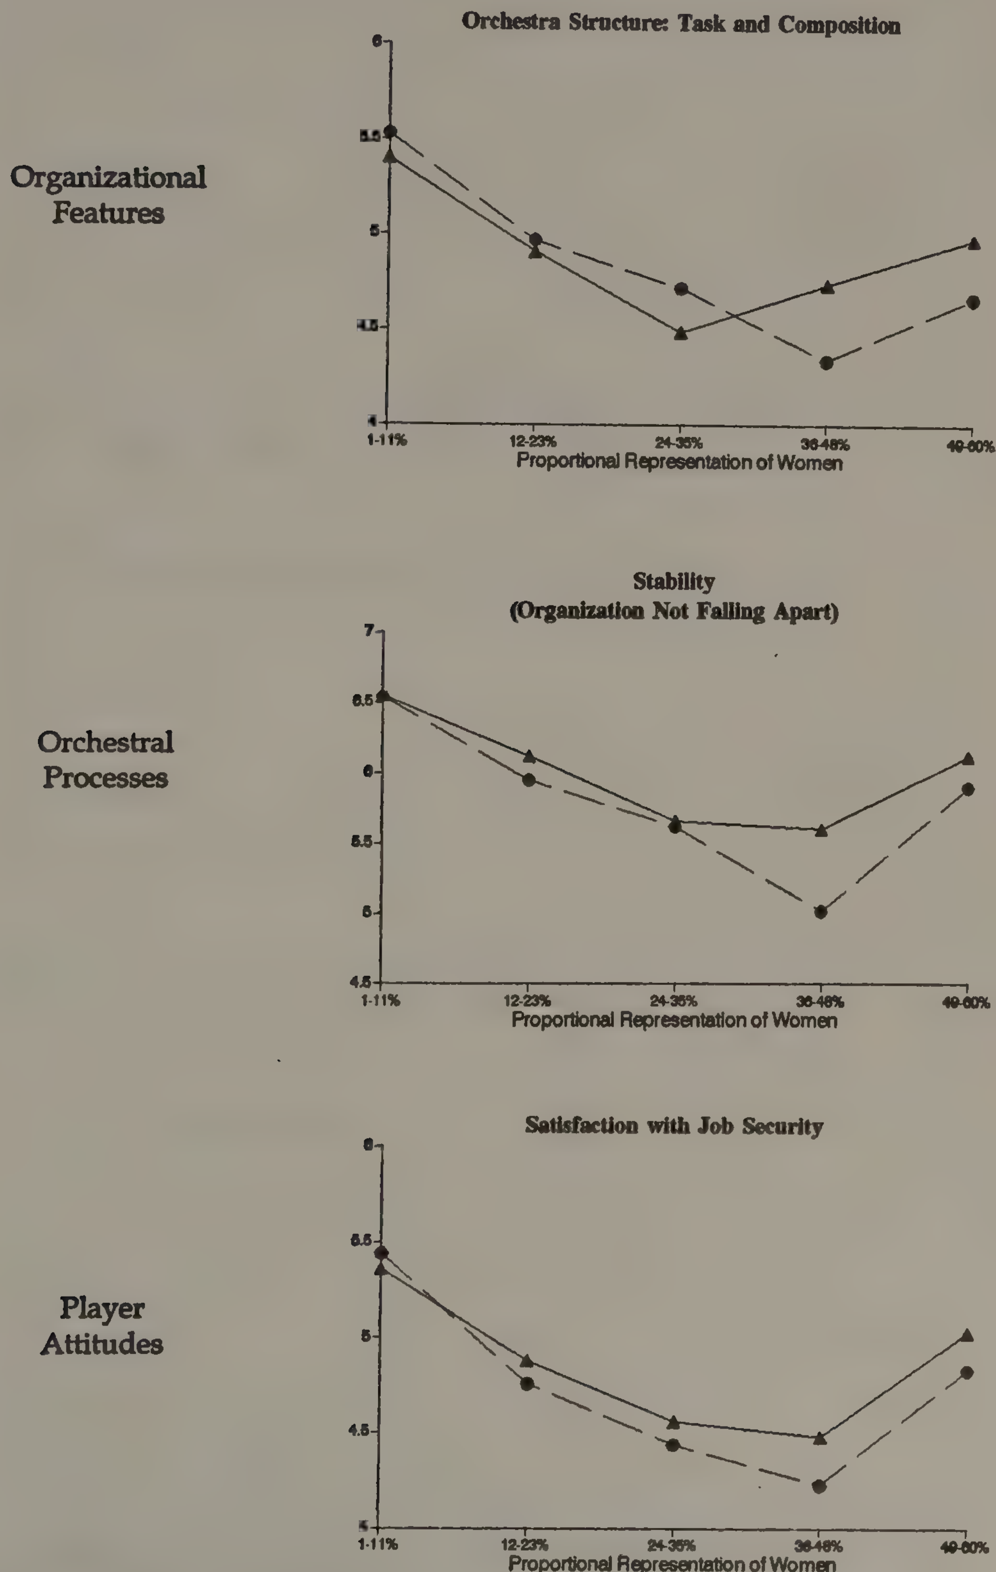

FIGURE 5: Proportion Effects for Major vs. Minor Orchestras

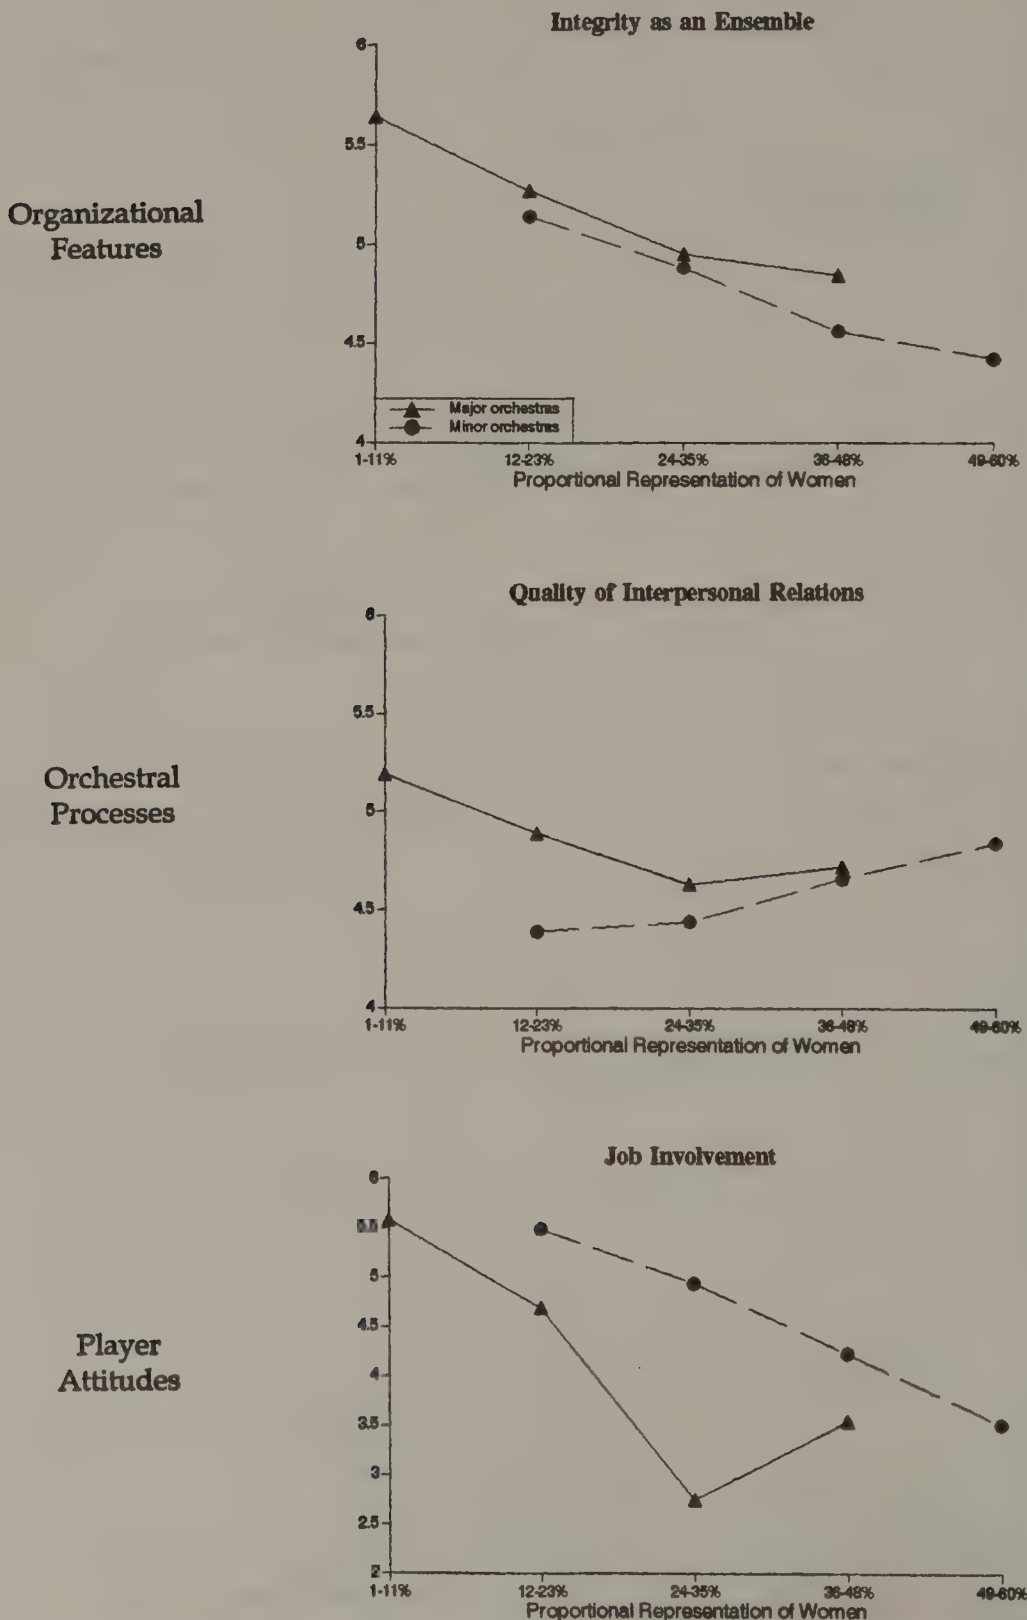

FIGURE 5: Proportion Effects for Major vs. Minor Orchestras (Continued)

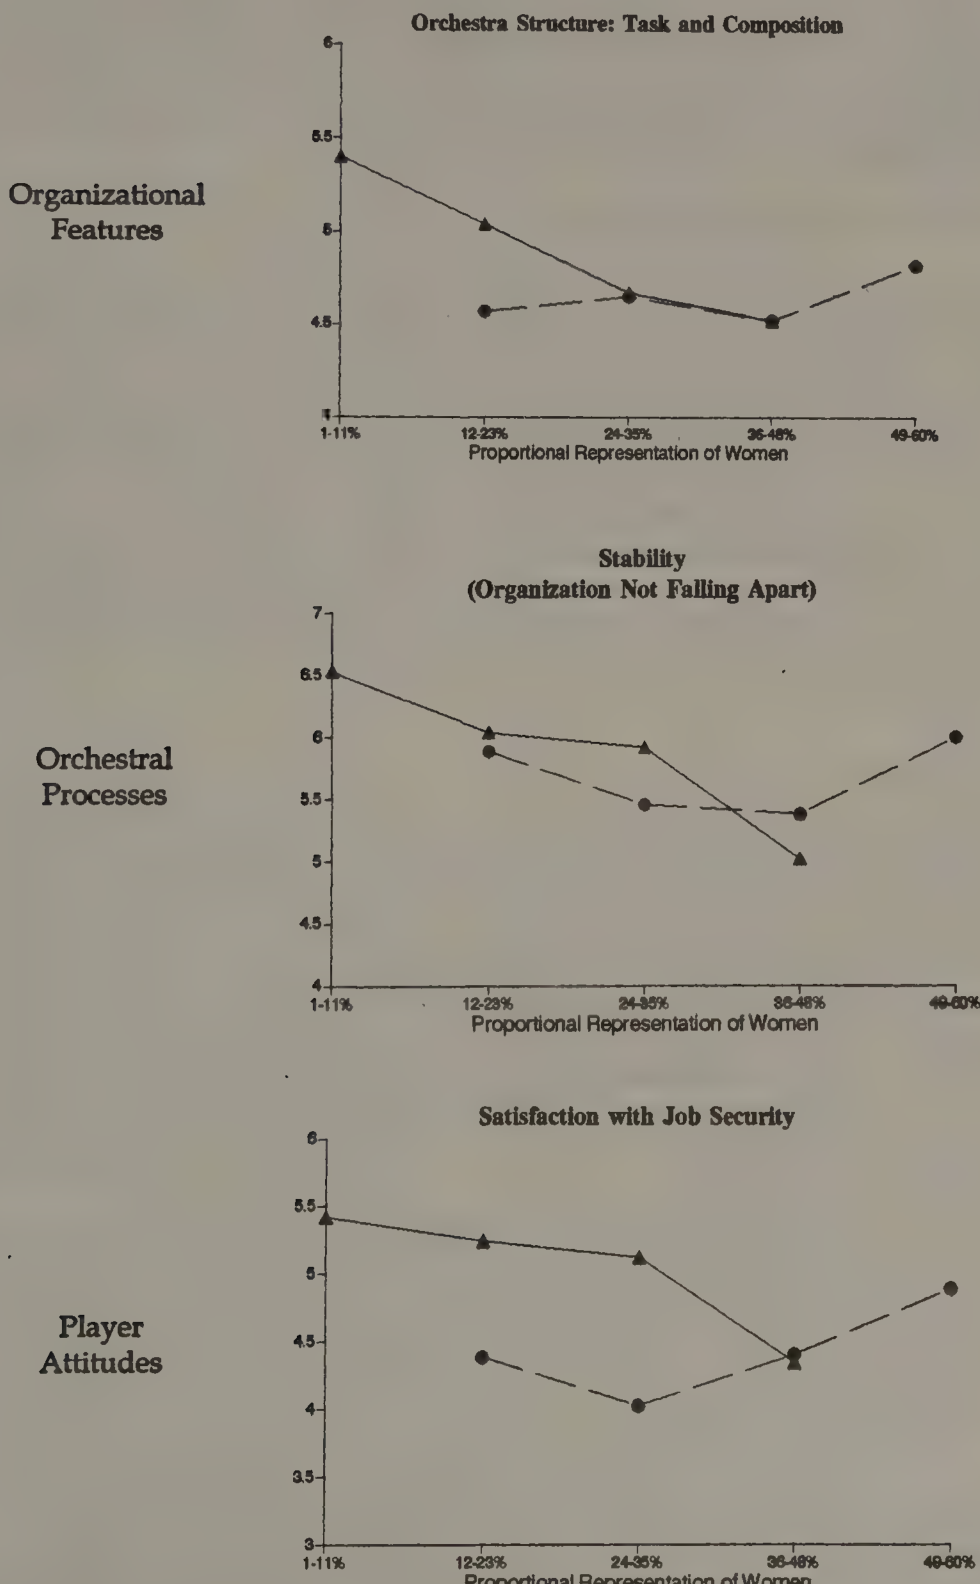

of the significant interactions is shown graphically for one variable, integrity as an ensemble, in Figure 6.[8]

It is noteworthy that for most of the dependent measures in Table 4, *both* men and women have higher scores at lower levels of female representation than at higher levels. This pattern, which is consistent with the main effect findings reported earlier, also fits with those of Wharton and Baron (1987, 1991), who reported that women as well as men are more satisfied with their jobs in male-dominated than in mixed work settings.

COMPOSITION-COUNTRY INTERACTIONS

Significant interactions between gender composition and country were obtained for 16 of the 22 dependent measures (see Table 2). Although effect sizes for these interactions are smaller than those of their component variables, they do suggest that the impact of changes in orchestra gender composition depend significantly on national context. Unfortunately, country-by-composition interactions necessarily involve twenty organization-level means (four countries by five proportions); given that our total sample of orchestras is 72, many cells that would be of great interest have only one or two entries — and a few have none at all. Therefore, we must rely mainly on archival and qualitative data to explore the mechanisms by which national contexts affect the dynamics and outcomes of the entry of women into symphony orchestras. We consider each country in turn.

United States

Orchestras in the U.S. more closely approach relatively balanced gender composition than do those in the other three nations. This country has had by far the most aggressive social policies of the four nations regarding equal employment opportunities. In addition, ICSOM (the union-related organization that serves players in major orchestras) some years ago mounted a campaign to improve the fairness of orchestra recruitment, audition, and selection processes. Union orchestras began to publicly advertise all open positions, to hold "blind" auditions (in which qualified applicants play behind a screen), and to significantly constrain the right of music directors to make employment decisions autonomously. The result has been a significant increase in the number of women in U.S. orchestras.

Minor orchestras in the U.S. are particularly informative because they are the ones for which gender composition is most balanced of all. Indeed, almost all the orchestras whose female membership exceeds 50% are minor orchestras located in U.S. Women in these orchestras have achieved a level of legitimacy and acceptance that, so far, is uncommon either in major U.S. orchestras or in orchestras in other countries.

Moreover, it is U.S. minor orchestras that are mainly responsible for the upturn at the end of the monotonic decline exhibited by many measures as the proportion of women increased. It is noteworthy that these improvements occurred despite the resource constraints that challenge virtually all minor orchestras. Although the dynamics of gender integration are likely to differ substantially for major and minor orchestras, it is possible nonetheless that

TABLE 4: Significant Interactions between Individual Gender and Orchestra Gender Composition[a]

		Proportion of Women (%)					F ratio (Gender by Proportion [Interaction])
		0-11	12-23	24-35	36-48	49-60	
Integrity as an ensemble	Men	5.72	5.35	4.97	4.59	4.19	5.0**
	Women	5.05	5.23	4.86	4.72	4.60

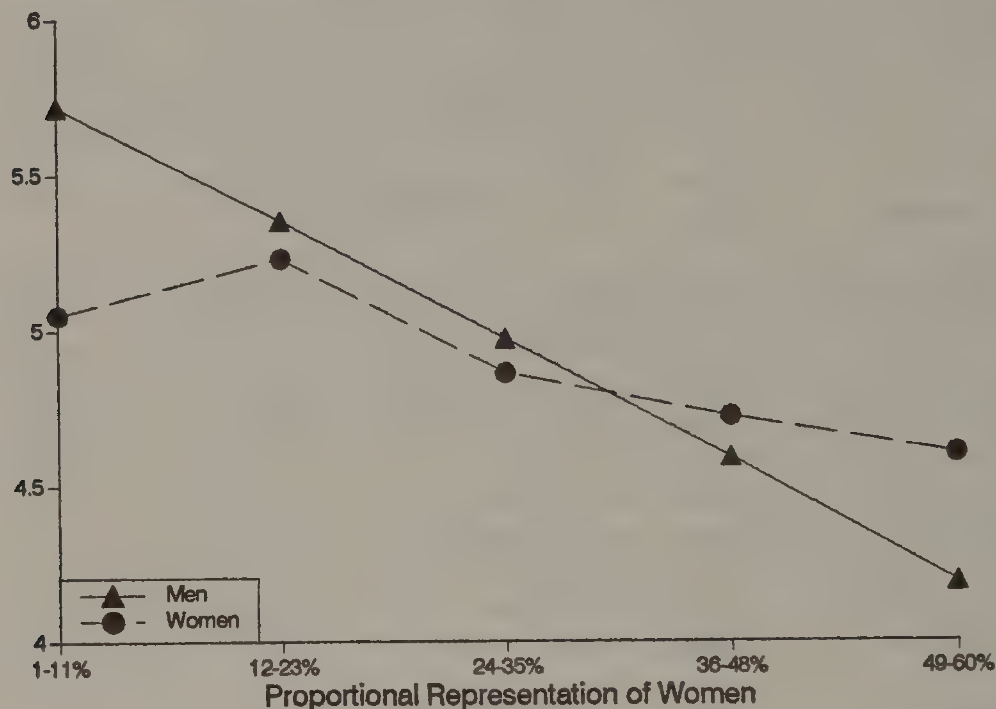
FIGURE 6: Gender-by-Composition Interaction for "Integrity as an Ensemble"



minor orchestras in the U.S. are providing an advance look at what eventually could become commonplace as female players achieve full legitimacy in symphony orchestras around the world.

United Kingdom

Although women are relatively well represented in British orchestras, their participation in the national labor force is considerably lower than in the U.S. Symphony orchestras in this country, then, are in the vanguard of the movement of British women into the work force and the professions.

The United Kingdom was unique among the nations studied in showing modest *improvement* in some scores on organizational features as the proportion of women increased. It may be that orchestra members, when comparing themselves to other British organizations, view themselves and their orchestras as doing rather well. And, one could argue, the larger the proportion of women, the more likely it is that orchestra members will have such perceptions.

A second explanation for the atypical relationship between proportion of women and certain of our measures derives from the player selection processes used by British orchestras. There are three relatively distinct groups of orchestras in the United Kingdom: (1) four major orchestras located in London, each a worker cooperative in which players are compensated on a "per service" basis; (2) six regional orchestras, not cooperatives, whose players hold annual

contracts, and (3) four British Broadcasting Corporation orchestras, all of whose members are civil servants. Because British orchestras generally do not use blind auditions, members know exactly who they are hiring and, especially in the London cooperatives and in the regional orchestras, pride themselves on selecting players who "fit in" with the orchestra — socially as well as musically. Moreover, since neither the government nor the musicians' union forces the hands of orchestras in hiring decisions, those women who are chosen for membership are likely both to be welcomed by the players who hired them and to have work styles that are generally congruent with the existing and predominantly male organizational culture.

Women in British orchestras, therefore, may be more inclined than their counterparts in other countries to perpetuate the existing orchestral culture — both in their behavior in the orchestra and when they participate in the selection of new players — than would women who had been selected solely on the basis of technical prowess. Women in British orchestras may not be adding as much diversity to their ensembles as would be the case if blind auditions were used. On the other hand, relations between male and female players almost certainly are more collegial than they otherwise would be — attested to by the fact that players in U.K. orchestras report higher satisfaction with work relationships than do players in any of the other countries in our sample (Allmendinger & Hackman 1992).

The future pattern of gender dynamics in British orchestras is far from certain. Significant tensions may develop as women approach majority status and men have to confront the fact that women's gains have occurred, to some extent, at their expense. Yet if the national as well as the orchestral work force eventually approaches gender balance, then player attitudes and relationships in these orchestras may look very much like what is now characteristic of many minor orchestras in the U.S.

East and West Germany

The situation in the former East Germany is almost the opposite of that in the United Kingdom. In the late 1980s, East German women had a higher rate of participation in the national work force, by a wide margin, than did women in any other country we studied — but symphony orchestras were still as they historically had always been, predominantly male. This fact highlights an exception to the general policy of "democratizing" the work force espoused by the leaders of the socialist state. Although women in the rest of East German society were given incentives to enter the work force and organizations were rewarded for employing them, this was deliberately not done for orchestras. Indeed, liberal government policies regarding leaves for childbirth and child care provided *dis*incentives for orchestras to hire women since substitute players were a scarce commodity. In East Germany, symphony orchestras became islands of male dominance in a sea of relative gender balance.

In West Germany, symphony musicians are civil servants paid with public funds. Although public policy dictates gender-blind employment opportunity, that policy has not been enforced for symphony orchestras. Moreover, the union that represents orchestra musicians has not actively promoted the entry of

women into orchestras. The result is that West German women have low rates of participation in *both* the national work force and in symphony orchestras.

These differences between the two Germanys allow empirical exploration of national-level influences on orchestral gender dynamics. In the German version of our survey, we included several items that asked specifically about the quality of gender relationships in respondents' orchestras (for details, see Allmendinger & Hackman 1993b). Findings for two of those items are informative. East German musicians agreed more strongly with the item, "In this orchestra, men and women support each other and work together toward common goals," whereas West German musicians were higher on the item, "Men and women are treated differently in this orchestra." Thus, even though the proportions of women in orchestras in the two German nations were almost identical, the gender *climate* was more favorable in East German orchestras, where women had a high rate of participation in the national work force, than in West German orchestras, where they did not. As also was found for the U.S. and the United Kingdom, we see that the national context does indeed affect how individuals respond to their local gender circumstances.

Discussion

There are large differences in the effect sizes of individual gender, organizational gender composition, and national context on the perceptions, attitudes, and motivation of orchestra players. Overall, respondent gender controlled less than 1% of the dependent variable variance. Members of a given orchestra in a given country, women and men alike, have attitudes that are far more similar to one another than they are to the attitudes of members of other orchestras. A symphony orchestra is a "strong situation" (Weiss & Adler 1984), in which institutional properties such as task demands and social norms are clear and powerful. These situational forces, apparently, dominate the influence of gender on members' affective reactions to their work.

This conclusion is reinforced by the findings for organizational gender composition (i.e., the proportion of members who are female) and for national context (i.e., differences among countries in their receptivity to women's participation in the national labor force). For our measures of member perceptions and attitudes, it is these structural and contextual variables that make the most difference.

ORGANIZATIONAL GENDER COMPOSITION

The traditional dictum, "the more, the better" as it applies to women entering traditionally male organizations is too simple. Our findings from symphony orchestras suggest that the problems encountered during the early stages of gender integration are unlikely to be resolved by simply increasing the proportion of women beyond token levels, a conclusion also reached by Wharton and Baron (1987:586). Although our findings are based on cross-sectional data, the interactions obtained between orchestra gender composition and both individual gender and national context make it possible to draw plausible conclusions about the dynamics of gender recomposition processes.

Specifically, our data suggest that gender dynamics differ qualitatively at three succeeding stages: (1) when an organization has but a token number of women (e.g., 10% or fewer female members), (2) when it is in transition (e.g., around 10-40% female), and (3) when it has become relatively gender balanced (e.g., 40-60% female).[9]

Organizations with Token Female Representation

Following Kanter's (1977a) pioneering study, it was generally accepted that the work life of male members of highly skewed organizations usually is quite satisfactory — but that the situation for their female colleagues is dissatisfying, stressful, and alienating. Our findings suggest that the picture may be more complex than that. Even though women are less satisfied with their orchestras and their work lives at token levels of representation, they are nonetheless more satisfied then than they are at the next higher levels of female participation.

It is no doubt true that, in male-dominated organizations, neither the organization nor its members are obtaining the benefits (such as personal learning and improved task performance) that compositional diversity can bring. Indeed, our qualitative data suggest that many women find that there are strong incentives for them to keep a low profile, to behave closely in accord with existing orchestral norms, and generally to be as nonintrusive as possible. This stance is costly to the orchestra because it protects majority members from exposure to unfamiliar perspectives and from the need to scrutinize and reconsider traditional behavioral norms. On the other hand, it increases the likelihood that the orchestra will run smoothly and it minimizes the kinds of tensions that characteristically develop when an orchestra moves into what we are calling the transitional stage of gender composition.

Organizations in Transition

Our findings show that organizational life for both female and male members takes a qualitative turn for the worse when the proportion of women reaches the transitional stage (i.e., 10-40%). For the first time, there are enough women to form a significant subgroup in the orchestra. Women now have a set of colleagues with whom they can share and test their perceptions, thoughts, and feelings (Zanna, Crosby & Lowenstein 1987). Moreover, it is now feasible for them to become a political force in the orchestra — something that is possible for a group, but rarely for an individual, in an established organization. And, as women become both more numerous and more powerful, men can no longer ignore the threat women pose to their occupational status and organizational control.

Together, these processes result in tightened identity group boundaries for both genders, increased cross-group stereotyping and conflict (Wharton & Baron 1987), less social support across gender boundaries (South et al. 1982), and heightened personal tension for everyone. These problems do not automatically correct themselves as the proportion of women grows; indeed, there are empirical as well as theoretical reasons to expect them to worsen as an organization moves through the transitional phase of gender integration (e.g., Blalock 1967; Taylor et al. 1978; Tsui, Egan & O'Reilly 1992). In our study, it was

not until women achieved a representation of over 40% that robust signs of improvement — the "tipping point" identified by Pfeffer and Davis-Blake (1987) — were first seen.

Relatively Balanced Organizations

In these organizations, all members have plenty of people like themselves with whom to do social comparisons and from whom to seek support. Moreover, members of both gender groups are likely to feel fully legitimate in the organization — neither closely scrutinized nor especially threatened. Under such circumstances, relationships between men and women should begin to stabilize. And with both constituent groups strong, it now becomes feasible to develop intergroup relations that are characterized more by interdependence and mutual support than by conflict (Smith 1982).

Our conclusion that such changes are not likely to be seen until after the proportion of female members exceeds 40% is identical to that reached by Martin (1985:329). And, even at that point, the monotonic decline seen for almost all our dependent variables continued unabated for four of them: three measures of members' perceptions of organizational features (the degree to which the orchestra has integrity as an ensemble, the degree to which players are recognized for good work, and the fairness and effectiveness of recruiting and auditioning practices) and the measure of individual job involvement. It remains an open question whether, at even higher levels of female representation, these measures also would have shown a reversal — and whether those measures that did reverse eventually would have surpassed the levels found in orchestras that had but token female representation.

CONCLUSION

To conclude, we step back and place our findings in larger context. What are the implications of the patterns we have reported for understanding, influencing, and researching the entry of women into organizations that have long been dominated by men? We propose three explanations:

(1) This is how the world works. Things really do get more difficult — for women, for men, and for the social system — as more women enter traditionally male organizations, at least until a state of gender balance is achieved. This generalization applies to all types of organizations and probably to all western cultures. Behavioral science interventions may be of some use in helping members of organizations undergoing demographic transition learn how to deal constructively with the increasing diversity that they are experiencing — but they are in opposition to natural social system forces.

(2) Symphony orchestras are unique. The type of organization we studied, the professional symphony orchestra, is unique in a number of ways. The work is to perform music. Accomplishing that work requires extraordinary levels of member coordination. Playing in a symphony orchestra is a high status profession, one with high barriers to entry. An orchestra is a true ensemble, but members work under the strong direction of a leader who is almost always male. And, as an institution, the symphony orchestra has a tradition of male exclusivity that is both longstanding and deeply rooted. It may be that

organizational gender composition would control less variation in attitudes in other types of organizations, such as schools or certain businesses, whose traditions are less strongly male and whose charters are not so unique. Moreover, the decline we found for many measures as the proportion of women increased might have been less steep, or might even have been reversed, in organizations with different gender traditions.

(3) A global transition in gender relations is occurring. There is a world of difference between a minor orchestra in the U.S. whose membership is 60% female and a major West German symphony that has but two or three female players. The former orchestra has completed its transition from male exclusivity to gender balance; the latter has still to begin. What we have in our findings, then, is but a snapshot of a moving phenomenon — and that phenomenon is proceeding at different rates for different types of organizations in different countries. Researchers can study the change process, interventionists can try to help it along, and managers can behave in ways that promote or impede it. But, in this view, gender recomposition in the workplace will inexorably move forward, regardless of what these and other professionals do.

The gender recomposition process is still underway in orchestras around the world and is at a relatively early stage in many of them. For this reason, it is not possible to rule out or to unambiguously affirm any of the three alternative explanations. Overall, we find the third alternative the most plausible and the most consistent with our evidence — but it will be necessary to wait for longitudinal data to become available before it can be definitively tested. Regardless of which interpretation one prefers, the present data do make clear that research done solely at any single level of analysis (be it the individual level, the organizational level, or the national level) and in any single nation is unlikely, by itself, to adequately explain and inform organizational gender dynamics. For it is in the *interactions* among personal, organizational, and contextual factors that the patterns of gender dynamics explored in this article come to life and play out their consequences.

Notes

1. Although Kanter's theory deals with men's and women's relative power and career opportunities as well as with their numbers, most studies prompted by her research have focused on the attitudes and experiences of token members (i.e., those whose subgroup consists of 15% or less of the total membership). Some subsequent findings support her propositions (e.g., Spangler, Gordon & Pipkin 1978; Yoder, Adams & Prince 1983); others do not (e.g., Fairhurst & Snavely 1983; South et al. 1982). Partly in response to these mixed empirical results, several alternative models of gender composition phenomena have been proposed in recent years. These models give relatively less emphasis to numbers and more to factors such as gender roles (Eagly 1987), expectation states (Ridgeway & Diekema 1992), and the structural features of social systems (Martin 1985).

2. It may be difficult for men to report, or even to explicitly acknowledge, such threats. Instead, as noted by one of the reviewers of this article, they may be more comfortable reporting that the organization does not function as well, or that it has a poorer climate, than publicly acknowledging that they are experiencing a threat to their status or control.

3. The power of the canon was especially evident in East Germany. Official policy during the socialist regime was for orchestras to emphasize in their programs the music of contemporary composers from socialist countries. To assess the impact of this policy, we selected one regular

concert program from each orchestra in our sample and noted the birth dates of the composers whose works were played. The median composer birth date for East Germany was 1809, compared to 1857 for West Germany, 1862 for the U.S., and 1864 for the United Kingdom. Despite official policy, East German orchestras continued to perform the standard repertoire — indeed, exhibiting greater commitment to the classical tradition than did orchestras in more market-oriented countries.

4. Kanter uses six categories to describe the proportional representation of women in organizations: uniform groups (no women), skewed groups (1-11% women), low-tilted groups (12-23%); high-tilted groups (24-35%), low-balanced groups (36-47%), and high-balanced groups (48-60%). For comparability with the numerous studies that use these categories, we also employ them in most of our analyses.

5. Assistance in enumerating the population of orchestras and in gaining access to them was provided by the American Federation of Musicians (AFM), the American Symphony Orchestra League (ASOL), the Arts Council of Great Britain (ACGB), the European Conference of Symphony Orchestras (ECSO), the International Conference of Symphony and Opera Musicians (ICSOM), and the Regional Orchestra Players Association (ROPA). We give special thanks to the following individuals: Kenneth Baird (ACGB), Brad Buckley (ICSOM), Rosemary Estes (ROPA), Catherine French (ASOL), Ken Haas (Boston Symphony Orchestra), and Lew Waldeck (AFM).

6. The three rival explanations are addressed serially because the analytic model required to assess them simultaneously generates an unacceptably imbalanced design (e.g., it generates a number of entirely empty cells). Nonetheless, an omnibus test was run to provide a rough assessment of the robustness of the main-effect findings for orchestra gender composition (Table 3). A hierarchical general linear model was constructed with gender composition entered as the penultimate term (i.e., after individual gender, orchestra standing [major versus minor], nation, age/experience, and sex-type of instrument [discussed later]; and before specific orchestra, treated as a random effect). This analysis yielded statistically significant gender composition effects for 18 of our 22 dependent variables (compared to significant effects for 19 of those variables in the main-effect analysis reported in Table 3). These findings affirm that significant gender composition effects remain even after those associated with other individual, organizational, and contextual factors are controlled. An additional omnibus analysis was run to assess the statistical reliability of the quadratic component of the main effect findings (i.e., the upturn found for some variables at the high end of the gender composition continuum). All quadratic effects found to be significant in the main analyses (reported in the rightmost column of Table 3) remain so after the control variables are introduced.

7. The composition of a full-size symphony orchestra is roughly as follows: 20 first violins, 20 second violins, 12 violas, 12 cellos, 10 basses, 16 woodwinds, 17 brass, and 4 percussion and other (Previn 1979, chap. 1). Gender differences across sections are substantial. In an analysis of the relative potency of section, orchestra standing (major versus minor), and country on the representation of women, section controlled 29% of the variance, compared to 14% and 6% for country and standing respectively.

8. This pattern does not hold for the two variables in Table 4 that have directly to do with musical matters — music director coaching and perceived musical outcomes. Women's reports for these two measures become increasingly favorable the larger the proportion of women in the orchestra, whereas men's reports exhibit no consistent pattern.

9. We do not address here either homogeneously male or dominantly female organizations because no such orchestras were in our sample. Reports about the Vienna Philharmonic Orchestra, one of the few remaining all-male professional symphony orchestras in the world, are that it is an orchestra whose members work together especially well as an ensemble (Blaukopf & Blaukopf 1986). It would be informative to compare the structure and functioning of that orchestra to an all-female ensemble.

APPENDIX

Measures Derived from the Player Survey

1. Organizational features of the orchestra

Integrity as an ensemble. The degree to which the orchestra operates as an intact, relatively stable ensemble, with clear and well-accepted norms of behavior. (8 items)

Orchestra structure: task and composition. The degree to which the work of the orchestra is well designed (i.e., the orchestra's tasks are challenging and rich in feedback) and the orchestra itself is well composed (i.e., players have a sufficient level and mix of talent and experience for their collective work). (5 items)

Player involvement and opportunities. The degree to which players have information and influence in the orchestra, share in its leadership, and have opportunities to improve their position within it. (8 items)

Adequacy of resources. The adequacy of the orchestra's facilities and material resources. (2 items)

Single items retained:

Recognition. "Excellent playing pays off in this orchestra."

Recruitment. "The orchestra's recruitment and audition process is fair and effective."

2. Behavior of the music director

Direction-setting. The degree to which the music director sets a clear and engaging artistic direction for the orchestra. (5 items)

Organizational initiatives. The degree to which the music director takes organizational initiatives (both internally, such as by working with management to improve the organizational structure or the recruitment process, and externally, such as by building community support or negotiating recording contracts). (7 items)

Coaching. The degree to which the music director makes himself or herself available to orchestra members and actively coaches individual players and sections. (5 items)

Single item retained:

Music director authority. "In this orchestra, the music director is the only *real* boss."

3. Orchestral processes

Quality of relationships. The quality of the working relationships among orchestra members. (7 items)

Musical outcomes. The degree to which the orchestra is improving (rather than slipping) musically. (3 items)

Single items retained:

Finances. "Our orchestra is getting stronger and stronger financially."

Stability. "As an organization, our orchestra shows signs of falling apart." (reverse scored)

4. Player motivation and satisfaction

General satisfaction. The respondent's overall satisfaction with his or her job and work. (3 items)

Internal work motivation. The degree to which the respondent is self-motivated to perform well (i.e., feeling good when having performed well, and feeling bad when having performed poorly). (3 items)

Job involvement. A single item: "I live, eat, and breathe my job."

Satisfaction with specific organizational features:
Compensation (2 items); Job security (2 items); Management (3 items); Work relationships (3 items); Growth opportunities (4 items)

Social Structure, Political Institutions, and Mobilization Potential

RORY MCVEIGH, *University of North Carolina at Chapel Hill*

Abstract

The increasingly diverse set of issues that form the basis of both traditional and nontraditional political activity has been attributed to the structural changes occurring in postindustrial societies. In the social movement literature, surprisingly little attention has been paid to the specific ways in which social structure, rather than structural change, impacts interest formation and interest articulation. In this article I argue that some forms of structural differentiation promote distributions of interests in which some interests cannot effectively be channelled into electoral politics. Variables measuring the structural differentiation of Colorado counties, in income inequality, educational inequality, ethnic heterogeneity, and industrial heterogeneity, are used to examine the relationship or the "fit" between party voting and voting on ballot initiatives concerning social or cultural issues.

Social movement theorists in the U.S. have focused considerable attention on the question of how a collectivity, given a common interest, organizes in pursuit of a collective good. Meanwhile, their European counterparts have primarily focused on group grievances and on the way in which structural change generates new mobilization potentials, that is, on groups of individuals sharing common interests that could be potentially activated by social movement organizers (see Cohen 1985; Klandermans 1984).

Renewed interest in group grievances and interest formation can be attributed to the increasingly diverse set of issues that form the basis of both traditional and nontraditional political activity. Many contemporary movements, such as those promoting women's rights, the environment, gay rights, and pro-life and pro-choice concerns, are not strictly engaged in distributive battles, but instead are promoting values or a collective identity. The proliferation in recent decades of social movement organizations that are not engaged in distributive battles, and that therefore do not fit neatly onto a one-dimensional left-right

I am grateful to Peter Bearman, Judith Blau, Peter Blau, Ken Bollen, Kathleen Harris, Garry Hoefle, François Nielsen, Tony Oberschall, Rachel Rosenfeld, Mim Thomas, and anonymous reviewers for their useful comments and suggestions. ***Direct correspondence to Rory McVeigh, Department of Sociology, Hamilton Hall, CB #3210, The University of North Carolina, Chapel Hill, NC 27599-3210.***

 Social Forces, December 1995, 74(2):461-485

continuum, forces social movement theorists to once again consider the origins of group grievances and interests.

In this article I explore the role of social structure in the promotion of interest distributions, which refer to how political preferences on various issues are distributed within a given community. I argue that some forms of structural differentiation within a community promote interest distributions where nonmaterial interests cannot be effectively channeled into established political institutions. The argument is tested through an analysis of party voting and voting on ballot initiatives concerning social or cultural issues in Colorado from 1980 through 1990.

INTERESTS AND SOCIAL CLASS

Studies of voting behavior in the U.S. have consistently shown a correlation between social class and party voting. Those of lower economic status tend to vote for the Democratic party, while wealthier individuals are more likely to vote Republican (Lipset 1981). Factors other than class, such as religion, ethnicity, and education, have tempered intergroup antagonism. The absence of one deep societal cleavage based solely on class position has contributed to political stability and reinforced the democratic process (Blau & Schwartz 1984; Coleman 1957; Coser 1956; Lipset 1981; Rae & Taylor 1970).

Lipset, and other students of politics, have argued that in recent years the ties between class position and party voting have weakened (Lipset 1981; see also Brint 1985; Glenn 1973; Knoke 1976; Weakliem 1991; Weiner & Eckland 1979). According to Lipset, there are now two lefts, the "materialist" and the "postmaterialist." The materialist left advocates policies promoting economic equality while the postmaterialist left is primarily concerned with cultural issues, values, or collective identities.

Similar statements have been made by researchers studying "new social movements."[1] Offe (1985), for example, claims that until the mid-seventies, "the traditional left-right continuum was an approximately adequate model in which all relevant political and societal collective actors could be located" (857). He, along with others, has argued that in postindustrial societies, social and cultural issues have become more important than economic issues. Inglehart (1987) links societal affluence in advanced industrial countries with a greater freedom to be concerned with values, rather than material well-being. In a similar vein, Offe (1985) claims that previously unarticulated interests which were once subordinated to class struggle within the political sphere are now expressed by increasingly large "decommodified" segments of the population.

In short, new social movement theorists have argued that the distinction between state and society has become blurred. Political institutions have become less and less capable of incorporating the multitude of interests that result from structural transformations of advanced industrial societies. The predominant role of the new, decommodified middle class in new social movements is offered as supporting evidence of arguments stressing structural change.

Clearly, the prevalence of contemporary movements is related to structural changes in modern societies. Support for such movements, no doubt, is also related to what Lipset (1981) describes as the social bases of politics. But less

attention has been paid to the effects of social structure itself. Does the way in which a community is differentiated in income, education, ethnic, and occupational distributions have an impact on interest formation that is independent of the levels of income, wealth, or education? What types of social structure promote interest distributions that cannot be channeled into established political institutions?

Interests and Institutions

The first question that arises is, why are interests, whether they are instrumental or noninstrumental, pursued through a social movement rather than through traditional political institutions. In regard to class-based movements, it has been argued that negatively privileged groups are denied access to political power and therefore must rationally pursue their interests through nontraditional political means (Gamson 1975; Jenkins 1985; Jenkins & Perrow 1977; McAdam 1982; McCarthy & Zald 1977; Oberschall 1973; Piven & Cloward 1979; Tilly 1978). But what about movements centered around social or cultural issues? The membership for many of these movements, for example the environmental or pro-choice movements, is disproportionately drawn from the middle class (Cohen 1985; Offe 1985; Weakliem 1991). If the polity is responsive to groups possessing resources, why do these groups pursue their goals through social movement activity rather than through traditional politics?

Skocpol (1992) calls attention to the "fit" between a group's political orientations and the established political institutions designed to incorporate those interests; what we might call the "overall structure of political opportunity" (Gamson 1975; Jenkins 1985; McAdam 1982; Tilly 1978). When there is a poor fit between a group's interests and the capacity of established political institutions (such as political parties) to address those interests, social movement activity might be expected. Shefter (1983) argues, for example, that "the very process of channelling political participation through established institutions and into the electoral arena contains participation and limits its disruptive effects" (483; see also Amenta & Zylan 1991; Clemens 1993). "Disruption," therefore, should occur when interests cannot be channelled through the electoral arena.

INCONSISTENT INTERESTS

Electoral politics forces individuals to attempt to reconcile all the interests that they hold with the platform of one political party, a task that is often difficult to accomplish. At the national level, the Democratic party appeals to the left on both social and economic issues, while the Republican party tends toward the right in both spheres.[2] That is, the Democratic platform, relative to the Republican platform, advocates more state intervention in the economy to promote equality. On social issues, the Republican platform promotes traditional values and beliefs, while the Democratic platform appeals to postmaterialist values (Lipset 1981).

The ideological positions adopted by the two parties are consistent in the sense that the Democratic party positions itself to the left of center on both economic and social issues and the Republican party is right of center on both

types of issues. Interests held by individuals or groups, however, may or may not be consistent. While some in the working class are drawn toward conservative parties based on their beliefs in traditional cultural values, parties of the left pick up voters from the middle class who favor liberal policies on issues associated with lifestyle, culture, and values (Brint 1984; Lipset 1981; Weakliem 1991).

When a voter's interests are consistent, those interests can be reconciled with the position taken by one of the two competing parties. There is a fit between interests and political institutions, hence there is a low demand for political action that circumvents the traditional political arena. Voters with inconsistent interests, however, must rank their interests by preference, voting for the party that maximizes their utility (Schattsneider 1960). In doing so, some of their interests cannot be satisfactorily channelled into electoral politics. In fact voters are, in effect, forced to vote against their own position on some of the interests that they hold. While such cross-pressures may indeed reduce the antipathy that individuals feel toward the other party (Lipset 1981), they also generate a large pool of individuals who should be receptive to organizations pursuing their "unrepresented" interests outside of the traditional political arena.

For social movement theorists, therefore, it should be important to understand what factors contribute to interest inconsistency. When a desired collective good has jointness of supply, which is the case when the collective good in question concerns values or identity, effective collective action does not require full participation from potential beneficiaries (Oberschall 1993). A critical mass of highly motivated actors can do the job, and as Marwell and Oliver (1993) have demonstrated, the larger the size of the mobilization pool, the more likely it is that such a critical mass will emerge. For postmaterialist social movements, a large mobilization pool should exist in communities where liberal sentiment on social issues substantially exceeds support for the Democratic party. Similarly, a large mobilization pool for conservative, nondistributive movements should exist where conservatism on social issues exceeds support for the Republican party.

Social Structure: Inequality and Heterogeneity

Drawing on the work of Peter Blau, I propose that interest inconsistency is related to variations in the social structure of local environments. Blau has written extensively on the impact of social structure on social relations. He argues that individual choices and preferences are constrained, to a great extent, by the social structure in which individuals are embedded. Social structure, using Blau's definition, is "the distribution of a population among positions in a multidimensional space" (Blau & Schwartz 1984:9).

Societies are differentiated by nominal distinctions such as ethnicity or occupation, but they are also differentiated by status gradations such as income or levels of education. At the individual level, a considerable amount of research has shown that people tend to associate with others who are most similar to themselves, in terms of both nominal and graduated parameters

(Abramson 1973; Alba 1976; Blau & Duncan 1967; Heer 1974; Hollingshead 1950). Paradoxically, Blau shows that at the societal level heterogeneity promotes intergroup relations and inequality increases the probability of status-distant relations. In a completely homogeneous society, for example, there is a zero probability of having intergroup relations, and when there are high levels of equality, there will be few status-distant relations.

These structural constraints should have an important impact on how views on economic policy and social policy coincide within a given community. In a community with little inequality, there is little contact between individuals of different status. Holding constant the absolute level of resources, the promotion of equality is unlikely to be a salient issue when inequality is low. Where there is high inequality, however, there are higher levels of status-distant contact. A minority of the population possesses a large share of the wealth or income, and the majority is relatively impoverished. The presence of inequality is likely to contribute to feelings of deprivation or injustice held by the underprivileged majority, generating a demand for redistributive policy (see Jasso 1980).

Differentiation on nominal parameters should have implications for the demand for public policies reflecting postmaterialist values. Liberalism on social issues addresses the rights of individuals, for example, the right of a woman to choose to have an abortion, or the right of a gay individual to serve in the military. Social conservatism, however, encourages conforming to established tradition or to the dominant values of society. Heterogeneity on nominal parameters within an individual's immediate environment, I argue, promotes individuality, while homogeneity promotes conformity.

As Blau and Schwartz state, cross-cutting cleavages that are characteristic of heterogeneous communities "produce a complex web of group affiliations, and individuals find themselves at the intersection of numerous groups. This creates cross pressures, which are stressful, but which also weaken the power of a given group to enforce restrictions on individuals, thereby expanding freedom of choice" (Blau & Schwartz 1984:84). In a homogeneous community, on the other hand, a limited role structure exerts pressure on the individual to conform to the dominant values of his or her immediate environment (Blau & Schwartz 1984; Durkheim [1933] 1984; Simmel 1950; Thomas 1994).

If the preceding logic is sound, it would seem that both inequality and heterogeneity should promote Democratic voting. In reality, however, we see many heterogeneous and unequal communities that vote Republican.[3] This is consistent with the arguments made by Lipset and by new social movement theorists that in modern industrial societies, cultural issues are becoming at least as important as class issues in the political arena. For this reason, it seems particularly important that we address the relationship between nominal and graduated parameters in the study of political interests.

Uncovering the net impact of inequality, however, requires holding constant the levels of heterogeneity. In the same manner, to assess the net impact of heterogeneity, levels of inequality must be held constant. The degree that nominal and graduated parameters intersect varies considerably from community to community. According to the argument made above, where there is both inequality and heterogeneity, there should be consistency. This type of structure fosters liberal sentiment in both the economic and social dimensions that can be

expressed through the Democratic party. There should also be consistency where there is homogeneity and equality. In this case the structural parameters do not foster a demand for either liberal economic policy or liberal social policy. This interest distribution can be effectively captured by the Republican party.

It is where the structural parameters work at cross-purposes that interest inconsistency arises. For instance, where there is inequality and homogeneity there should be a demand for policies promoting economic equality, but little demand for social liberalism. Or, when a community is characterized by equality and heterogeneity, there should be support for economic conservatism, but a demand for liberal policies on social issues. Neither of these combinations can be reconciled with the platform of one of the two major parties. These predictions can be summarized in the two-way Table 1. I refer to communities where there is social conservatism but economic liberalism as "social reactive" and to those communities where there is social liberalism and economic conservatism as "social proactive."[4]

The Data

I use ballot initiative voting not as a measure of social movement activity, but instead as a way of measuring the fit between party voting and positions on social issues. Initiatives and referenda have increasingly been used as a means of pursuing and expressing interests outside of party politics (Hahn & Kamieniecki 1987). The costs and effort required to put an initiative on the ballot are small relative to the costs entailed in starting a new and viable political party. Initiatives allow individuals or groups to bypass traditional politics, putting their position before the general public. They provide voters holding inconsistent interests with the freedom to remain within the party based on one set of preferences, but act outside of the party on other interests.

In the 1980s, several initiatives appeared on Colorado ballots centering on issues that cannot be considered as strictly distributive battles. All these issues have been, in some form, addressed in the social movement literature. They include abortion (Clarke 1987; Eckberg 1988; Leahy & Mazur 1978; Luker 1984; Staggenborg 1988, 1989), gambling or vice (Beisel 1990; Gusfield 1963; Wood & Hughes 1984), the environment (Barbosa 1993; Mitchell 1979; Modavi 1991; Offe 1990), restrictions on the sale of alcohol (Gusfield 1963; Unnithan & Corzine 1987), and multilingualism (Laczko 1987; Nielsen 1980; Olzak 1982). These issues, of course, also contain an economic component, but in each one, culture, identity, and ideology play central roles.

Counties in Colorado are used as units of analysis; they reflect considerable structural diversity in income, educational levels, occupational distributions, and ethnic composition. I include eight ballot initiatives in the analysis, and these represent all the initiatives appearing on the November ballot in Colorado from 1980 through 1990 that concern social or cultural issues. Democratic voting is operationalized as each county's percentage of votes for the Democratic candidate for the U.S. Senate, averaged across the four elections held from 1980 to 1990.[5] A description of the eight initiatives and their outcomes is provided in

TABLE 1: Structural Differentiation and the Demand for Liberal or Conservative Social and Economic Policy

	Homogeneity	Heterogeneity
Inequality	Social Conservative and Economic Liberal (Social Reactive)	Social Liberal and Econimic Liberal (Consistent)
Equality	Social Conservative and Economic Conservative (Consistent)	Social Liberal and Economic Conservative (Social Proactive)

Table 2. Pearson correlations and univariate statistics for Democratic voting and the initiative results are shown in Table 3.

The correlations reported in Table 3 show that the liberal position on ballot initiatives tends to be associated with Democratic voting. This is the case in seven of the eight initiatives used in this study. In the eighth initiative (gambling in 1990), party voting has no correlation with proposition voting. There is a particularly strong positive correlation between Democratic voting and support for bilingualism ($r = .688$).

In addition to party voting and initiative voting, there are several relatively strong correlations among the voting results of the initiatives. As would be expected, there is an extremely high correlation between the two abortion initiatives (.921). There is also a high positive correlation between the proabortion stance and the prolottery stance (.738). Voting "yes" on the proalcohol initiative is highly correlated with voting "yes" on the proenvironment issue (.707). Other correlations among the ballot initiatives are weaker.

While liberal voting on ballot initiatives does tend to be associated with Democratic party voting, the fit is far from perfect. This study uses the voting data that have been presented to form a measure of interest inconsistency. Variables reflecting structural differentiation of counties are then used to examine the relationship between structural differentiation and interest inconsistency.

THE DEPENDENT VARIABLE

A ratio measure is used to capture the fit, or lack of fit, between interests on social issues and party voting. For each ballot initiative, the county's percentage vote for the liberal stance is first divided by the sample mean. I then divide this ratio by the county's Democratic voting percentage divided by the sample mean. This ratio of two ratios provides a measure of the extent to which a county's support for the liberal position on ballot initiatives exceeds or is less than its support for the Democratic party. The numerator measures the extent to which a county favors the liberal position on a given social issue, relative to

TABLE 2: All Colorado Initiatives Concerning Social Issues That Appeared on November Ballots from 1980-1990

Initiative	Sponsor's Position	Outcome	Description
Amendment 2, 1980	Liberal	59.9% in favor	Amendment to change state constitution's antigambling clause, to allow for legislative creation of a state lottery
Amendment 5, 1982	Liberal	26.5% in favor	Would require 5 cent deposit on beverage bottles and cans. It would also ban detachable pop tops and nonbiodegradable ring carriers.
Amendment 7, 1982	Liberal	34.6% in favor	Would allow grocery stores to sell wine.
Amendment 3, 1984	Conservative	50.4% in favor	Would prohibit publically funded abortions.
Amendment 5, 1984	Liberal	33.6% in favor	Would permit casino gambling in Pueblo, Colorado.
Amendment 1, 1988	Conservative	60.8% in favor	Would make English the official language in Colorado, and would place restrictions on speaking other languages, for government employees.
Amendment 7, 1988	Liberal	39.8% in favor	Would repeal ban on using state money for abortions.
Amendment 4, 1990	Liberal	57.6% in favor	Would allow limited stakes gambling in two historic mining towns in Gilpen County.

(N=63)

[a] Colorado counties are the units of analysis.

the vote of other counties. The denominator is a measure of the relative support for the Democratic party.[6] A high value on the overall measure, then, signifies that the county is more liberal on the social issue in question than would be expected based on its party voting (social proactive). A low value, on the other hand, means that the county is more conservative on social issues than party voting would suggest (social reactive). Values close to 1 indicate consistency between party voting and voting on initiatives.

INDEPENDENT VARIABLES

Four variables are used as measures of the structural differentiation of the counties: income inequality, educational inequality, ethnic heterogeneity, and industrial heterogeneity. I also control for median income, median years of education, party competitiveness, and population density. See Table 4 for the method of calculation for each variable and the source of the data.

Income Inequality and Educational Inequality

Based on the previous discussion, I expect that both income inequality and educational inequality will be negatively related to social proactive voting. I have argued that inequality on graduated parameters promotes a demand for liberal economic policy, but not necessarily liberal social policy. Holding the counties' level of heterogeneity constant, therefore, inequality should be associated with more social conservatism than would be expected based on party voting, while equality should be associated with more liberalism on social issues than party voting would suggest.

Industrial Heterogeneity and Ethnic Heterogeneity

As previously argued, heterogeneity on nominal parameters such as ethnicity and occupation should have a positive impact on social proactive voting. The presence of many cross-cutting cleavages fosters individualism, which is consistent with liberal or postmaterialist values, while a limited role structure exerts pressure towards conformity. Holding constant the level of inequality, heterogeneity should be associated with higher levels of social liberalism relative to Democratic voting, and homogeneity should be associated with lower support for social liberalism relative to Democratic voting.

CONTROL VARIABLES

Party Competitiveness

I control for party competitiveness since environments in which one party dominates should be conducive to the formation of new political parties purely from an ecological standpoint. In such a case, the dominant party occupies an expanded niche and is vulnerable to losing its peripheral supporters (see Nielsen 1986; Pinard 1975). Since there are several barriers to third party formation in the U.S., those interests that a third party might address, such as different combinations of liberalism and conservatism, might be expressed through other means. Since most of the counties in Colorado have Republican

TABLE 4: Definitions of Independent Variables and Sources of Data

Income inequality: Data on family income are taken from Table 180 of the 1980 U.S. Census of Population. The census presents the income distribution for Colorado counties in 9 categories. The categories are (1) less than \$5,000, (2) \$5,000-\$7,499, (3) \$7,500-\$9,999, (4) \$10,000-\$14,999, (5) \$15,000-\$19,999, (6) \$20,000-\$24,999, (7) \$25,000-\$34,999, (8) \$35,000-\$49,999, and (9) more than \$50,000. To calculate the Gini coefficient, a Pareto interpolation is first used to estimate the average income in categories above the category containing the median income (see Nielsen & Alderson 1993). The coefficient is then calculated using the formula provided by Nygard and Sandstrom (1981).

Educational inequality: In Table 175 of the 1980 census, years of education for persons 25 years and older is aggregated into 8 categories. The categories are (1) 0-4 years, (2) 5-7 years, (3) 8 years, (4) 9-11 years, (5) 12 years, (6) 13-15 years, and (8) 17 years or more. In calculating a Gini coefficient, the average is estimated as the midpoint of each category. I assume that the average of the open ended category is 19 years of education.

Industrial heterogeneity: Industrial heterogeneity is measured using the 11 primary industry categories of employment reported in the 1980 census, Table 178. These categories are (1) agriculture, (2) forestry and fishery, (3) mining, (4) construction, (5) manufacturing, (6) transportation, communications, and other public utilities, (7) wholesale trade, (8) retail trade, (9) finance, insurance, and real estate, (10) services, and (11) public administration. The heterogeneity measure is calculated as $1 - \Sigma P_i^2$, where P_i is the fraction of the population in each group (Blau 1977).

Ethnic heterogeneity: Data for ethnic heterogeneity comes from table 178 of the 1980 census. Five categorical groupings are used. They are (1) white (not Spanish origin), (2) black (not Spanish origin), (3) Spanish origin, (4) American Indian, and (5) Asian. The heterogeneity measure is calculated in the same manner as for industrial heterogeneity.

Party competitiveness: I use the earlier described measure of voting for U.S. Senate campaigns to construct a measure of party competitiveness. The measure is constructed in the same manner as the heterogeneity variables. Only two categories, Democratic voting and Republican voting, are used. In Colorado, support for any other party in senate campaigns was either minimal, or nonexistent.

Population density: Population density is measured with the natural log of the population per square mile, as reported in Table 2 of the 1980 census.

Median income: County-level median income is taken from Table 189 of the U.S. census.

Median years of education: County-level median years of education is taken from Table 175 of the U.S. census.

majorities, party competitiveness is likely to be negatively related to proactive voting. That is, in most cases noncompetitiveness means a large Republican majority, thereby placing a limit on the extent that conservative initiative voting can exceed voting for the Republican party.

Population Density

Population density captures the extent that counties are urbanized. Population per square mile is also related to opportunity for contact — a key assumption of Blau's (1977) theory. Any type of social relations, favorable or hostile, are dependent upon propinquity.

Median Income

To ascertain the impact of structural differentiation on interest inconsistency, it is necessary to control for absolute levels of wealth or income of the counties. It could be argued, for example, that measures of income inequality merely serve as a proxy for the relative wealth or poverty of the counties. Several voting studies have called attention to the phenomenon of upper-status economic conservatism and social liberalism (Brint 1984; Hamilton 1975; Huber & Form 1973; Lipset 1981; Robinson & Bell 1978). It should be expected that median income will have a positive impact on proactive voting.

Median Years of Education

It is particularly important to control for the median level of years of education since a large body of research has documented a strong positive relationship between education and liberalism on social issues (see Hyman & Wright 1979; Lipset 1981; Nunn et al. 1978).[7]

Methods

I begin by examining the relationship between social structure and the broad concept of interest inconsistency. Subsequently I focus on the extent to which these structural variables contribute to our understanding of interest inconsistency on the specific issues. More emphasis is placed on the broader concept. Political representatives, after all, must attempt to address a wide array of constituent interests and preferences. Analyzing all eight issues simultaneously will shed light on how structural differentiation impacts the fit between party voting and the many dimensions of social liberalism. Nevertheless, it is also useful to examine the relationship between social structure and interest inconsistency on the specific issues. For example, do measures of inequality and heterogeneity help us understand why some counties have strong support for the Democratic party, yet strongly oppose abortion funding?

A panel design is used to analyze all the initiatives simultaneously. Essentially, the ballot initiative votes represent eight cross-sections for the 63 Colorado counties. The dependent variable in each cross-section is the measure of the counties' social proactiveness. To control for possible effects of the substance of a ballot initiative on proactiveness, I use a fixed effects model. In this approach, initiative specific dummy variables corresponding to each panel

are inserted, measuring the shifts in the regression line that may result from unknown variables associated with the specific issues (see Kennedy 1992:222). The model is estimated as

$$Y_{it} = \alpha_1 d_{2it} + \ldots + \beta' X_{it} + \epsilon_{it}$$
$$= \alpha + \beta' X_{it} + \epsilon_{it}$$

where Y_{it} is the proactiveness of county i on ballot t, X_{it} is a vector of independent variables for county i at ballot t, β is the vector of regression coefficients, the α_i's are initiative specific constants, and the d_j's are the eight issue specific dummy variables which equal 1 only when $j = i$. (Greene 1992).[8]

The matrix of Pearson correlation coefficients in Appendix A shows that there are high correlations between the income and education control variables and the educational inequality measure. The zero order correlation between median income and educational inequality is -.795, and the correlation between median years of education and educational inequality is -.819. Therefore, three models are presented. In the first model, only the control variables are used. In the second model, the structural variables are added but median income and median education are omitted. In the third model, all the variables are included.

After examining the impact of structural differentiation on proactive voting when all of the issues are considered simultaneously, I apply the full model to each initiative. Ordinary least squares regression is used to estimate eight separate models. The dependent variable for each model is calculated in the same manner as in the panel design, capturing the extent that liberal voting on the social issue exceeds support for the Democratic party.

Estimating each vote separately substantially reduces the degrees of freedom. This could be a problem since median income, median education, and educational inequality are highly correlated. As a conservative test on the structural variables, however, I include both median education and median income in the model. The effects of the structural variables, after all, are likely to be associated with the absolute levels of income and education.

The Findings

THE BROAD CONCEPT OF SOCIAL LIBERALISM

The results of the pooled models are reported in Table 5. In model 1, 21% of the variation in social proactive voting is explained by the control variables. Party competitiveness has the expected negative impact on social proactiveness. In other words, the more party competitiveness within the county, the less support for social liberalism relative to support for the Democratic party. Both median income and median years of education have the anticipated positive effect.[9]

In the second model, where the structural variables are added and median income and education are left out, the R^2 increases to .280. Income inequality, which I expected to have a negative effect on proactiveness, is not statistically significant, although the sign of the coefficient is in the expected direction. As was the case in the first model, party competitiveness is negatively related to social proactiveness. Population density also has a strong negative effect,

perhaps because the more urbanized areas tend to have the strongest support for the Democratic party. After controlling for ethnic and industrial heterogeneity, which are also typical of urbanized areas, there is less support for social liberalism relative to support for the Democratic party in densely populated counties.

As predicted in Table 1, ethnic and industrial heterogeneity are both positively related to social proactive voting. Holding the other variables constant, the more heterogeneous the county, the greater the support for social liberalism relative to Democratic voting. The more homogeneous the county, the more support for social conservatism, relative to support for the Republican party. Educational inequality also has the anticipated negative impact on social proactive voting. Net of the effects of the other variables, educational inequality promotes less support for social liberalism relative to support for the Democratic party. Educational equality, on the other hand, fosters more social liberalism relative to Democratic voting.

In the full model, where all the control variables are included, median income and median education are no longer significant at the .05 level (most likely due to the high correlation between these variables). The inclusion of these controls, however, does not eliminate the statistical relation between the structural variables and social proactive voting. Once again, income inequality is not statistically significant. The relationships for the other variables remain strong. Party competitiveness and population density are negatively related to social proactive voting, as is educational inequality. Occupational heterogeneity and ethnic heterogeneity have the expected positive relation.[10]

The partial coefficient for the ethnic heterogeneity variable calls attention to the importance of the control variables in each model. The zero-order correlation between proactive voting and ethnic heterogeneity is negative ($r = -.236$), yet the results of multivariate analysis show the predicted positive relationship between these variables. Since ethnic heterogeneity is at least moderately correlated with most of the variables in the analysis, multivariate analysis is needed to assess the net impact of this variable. For example, ethnically heterogeneous counties tend to have lower median income and median education. They also tend to have more party competitiveness and educational inequality.

While it is important to control for these other variables, the strong correlations between some of the variables introduces a potential problem of multicollinearity. To assess the extent that the findings are robust, I begin by running a model without the control variables. As shown in Table 6, educational inequality and industrial heterogeneity are highly significant in the predicted direction. Income inequality is not significant, and the coefficient for ethnic heterogeneity, while no longer negative, is insignificant.

Next, I present several models including three of the four control variables (I drop median income from the analysis due to its high correlation with median education). Then, controlling for population density, party competitiveness, and median years of education, I add the structural variables to the model one at a time, beginning with ethnic heterogeneity.

As shown in the second column of Table 6, the relationship between ethnic heterogeneity and social proactive voting becomes positive, and has borderline

significance ($p = .058$), after controlling for population density, party competitiveness, and median education. Interestingly, when income inequality is added to the model, as shown in model 3, not only does the impact of ethnic heterogeneity become stronger, but income inequality also has the anticipated negative impact on proactive voting ($p = .002$). When occupational heterogeneity is added in model 4, the observed effects of ethnic heterogeneity and income inequality remain intact, and occupational heterogeneity has the predicted positive effect. It is when educational inequality is added to the model (model 5) that the relationship between income inequality and proactive voting is no longer statistically significant.

THE SPECIFIC ISSUES

In this section I examine the extent to which the structural variables can explain proactive voting on each specific issue. As a conservative test, I include both median income and median education as controls. The results are reported in Table 7.

These findings show that with only three exceptions, out of a possible 32, the signs of the coefficients for the structural variables are in the expected direction. Contrary to my argument, income inequality has a positive sign on the environmental issue and on the bilingualism issue. Industrial heterogeneity is unexpectedly negative on gambling in 1990. The coefficients are in the expected direction for the other 29 possibilities. As for the control variables, the coefficient for party competitiveness is consistently negative. The coefficient for population density is also negative on all eight issues. Median education yields 6 positive coefficients, while median income yields 5.

The effects of the structural variables are particularly strong for the environment and alcohol votes. For these issues, income inequality is the only structural variable that is not statistically significant at the .05 level. At least one of the structural variables is significant at the .05 level in all the models, with the exception of abortion in 1984. Both educational inequality and industrial heterogeneity are significant predictors of proactive voting for the 1988 abortion initiative, but are not significant for the 1984 abortion vote. For abortion, the median levels of education and income are significant in 1984, while in 1988 they are not. A larger study population would be useful in separating out the effects of variables measuring absolute levels of income or education, and variables measuring the distribution of income and education. As in the pooled model, I examine the stability of the partial coefficients by controlling for party competitiveness, population density, and median education, and then adding each structural variable one at a time. The partial coefficients and probability values are reported in Appendix C.[11]

Holding all else constant, income inequality does not seem to have much of an effect on most of the issues. Income inequality is, however, a significant predictor for gambling in 1990. The educational inequality measure, on the other hand, is statistically significant at the .05 level on three of the eight issues, and is significant at the .10 level on gambling in 1988. Even after controlling for median education and median income, educational inequality has a negative impact on social proactive voting on the environmental issue, the alcohol issue,

the 1988 abortion issue, and the 1988 gambling issue. Industrial heterogeneity is significant at the .05 level on four of the eight issues. This variable has the expected positive impact on the lottery issue, the environment issue, alcohol, and the 1988 abortion issue. Finally, ethnic heterogeneity is positive and highly significant on the environment, alcohol, gambling, and bilingualism votes.

Discussion and Conclusion

The preceding analysis sheds light on the relationship between structural differentiation and interest distributions in the state of Colorado. The findings also point to several important research questions that could be pursued in future work. First of all, the results of this analysis suggest that it is important to consider the impact of structural differentiation on the formation and articulation of political interests. I have argued that inequality within a community fosters a demand for redistributive economic policy, while equality does not. Heterogeneity promotes a demand for liberal social policy, while homogeneity does not. When heterogeneity coincides with inequality within a community, or when homogeneity coincides with equality, interests can be effectively represented by the two competing political parties. When heterogeneity and inequality work at cross purposes, however, there should be a large pool of individuals who cannot channel all their interests into electoral politics.

In support of this argument the findings of this analysis show that holding the other variables constant, industrial heterogeneity and ethnic heterogeneity promote greater support for social liberalism relative to support for the Democratic party, when the eight initiatives are considered simultaneously. Also, the greater the educational inequality, the less support for social liberalism relative to support for the Democratic party. Income inequality, however, does not have a significant impact after controlling for educational inequality.

Looking at each initiative separately, it is clear that depending upon the issue, different structural variables come into play. The argument presented in this article receives the strongest support when considering the environmental issue and the alcohol issue, where educational inequality, occupational heterogeneity, and ethnic heterogeneity have the predicted effect. But on six of the eight initiatives, a test of the joint significance of the four structural variables is significant at least at the .05 level. The exceptions are the 1980 lottery vote and the 1984 abortion vote. Also, for seven of the eight initiatives, at least one of the structural variables is statistically significant and in the expected direction, the exception being abortion in 1984.

The failure of the structural variables to predict interest inconsistency on the 1984 abortion vote brings up an important point. On this issue, more than any of the others, religion plays a role that is not captured in the model. On the one hand, industrial heterogeneity intersects with gender, promoting a proactive gender identity at odds with a more traditional view of a woman's role in society (see Luker 1984). But in Colorado, ethnic heterogeneity usually means a high proportion of Mexican Americans, who are more likely than the other ethnic groups to have a religious affiliation (Catholicism) that is in conflict with the proabortion position. It is not surprising, in this case, that ethnic heteroge-

neity does not have the expected effect. Even so, it should be noted that on the 1988 abortion vote, educational inequality and industrial heterogeneity do play a role in explaining interest inconsistency.

Finally, the limited effectiveness of the income inequality variable is particularly interesting. While inequality does seem to affect interest inconsistency, it is educational inequality rather than income inequality that is important. Consistent with Lipset's description of a "postmaterialist left," this finding could reflect the declining significance of economic class in advanced industrial democracies and the increasing importance of cultural capital embodied in higher education. In the pooled model and in the models predicting interest inconsistency on the environment, alcohol, and the 1988 abortion issues, educational inequality had a highly significant negative impact on proactive voting. In other words, in those counties where a relatively small proportion of the population had access to higher education, there was more social conservatism than would be expected based on the proportion of the counties' vote for the Democratic party.

In such counties where interests are "inconsistent," there should be a mobilization pool that could be tapped by social movement activists pursuing nonmaterial interests. In some Colorado counties, popular sentiment is conservative on social issues, yet the county votes Democratic. In other counties, there is predominantly liberal sentiment on social issues, but the county nevertheless votes Republican. These counties would probably be receptive to movement organizations that provide a means for expressing unrepresented interests outside of traditional political institutions.

Social movements are one possible response to interest inconsistency. Other responses might be increased use of ballot initiatives and referenda, the formation of new political parties, or realignments within the dominant parties. Whatever the response, our understanding of both traditional and nontraditional political action should be enhanced by studying the relationship between social structure, political institutions, and mobilization potential.

Notes

1. While much of this research has originated in Europe, social movement organizations promoting values or collective identities are not missing from the American political landscape.

2. While political organization takes place at many levels, it is difficult for individuals to escape the impact of state or national level policies on issues such as abortion, the environment, gay rights, and economic policy.

3. In fact in this study of Colorado county level voting, I find no zero-order correlation between party voting and variables measuring inequality. Using the measures described later in the article, the correlation between Democratic voting and income inequality is -.011 and the correlation between Democratic voting and educational inequality is .054. Ethnic heterogeneity does show a strong positive correlation with Democratic voting (.447), but the correlation between Democratic voting and industrial heterogeneity is -.167.

4. Tilly refers to movements seeking to reassert established claims as reactive, while movements attempting to secure new benefits are proactive (Tilly 1978).

5. I use this measure, as opposed to party registration figures, because it provides a measure of how people actually vote when confronted with a choice between two candidates of the major competing parties.

6. For example, on the 1984 initiative to prohibit public funding of abortions, the mean county level vote in favor of the liberal position (not prohibiting public funding) is 45.54%. The mean vote for the Democratic voting variable is 40.3%. In Denver county, 58.4% favored the liberal position on abortion, and 57.1% voted Democratic. The dependent variable is calculated as:

$$\frac{58.4/45.54}{57.1/40.3} = .901.$$

In Denver county, voting on social issues and party voting are fairly consistent, with the county being somewhat less liberal on the abortion issue than party voting would indicate. For the same initiative, Arapahoe county provides an example of social proactive voting. Here, 52.3% favored the liberal position on the abortion issue, but Democratic voting is only 38.1%. Using the method of calculation described above, this county scores 1.22 on the dependent variable. Castilla county exhibits social reactive voting on this issue. Only 36.9% favored the liberal position on abortion, while 63.5% voted Democratic. Castilla county scores .52 on the dependent variable.

APPENDIX B: Aggregate OLS Models: Average Score on Proactive Voting for Colorado Counties on Eight Ballot Initiatives

	1	2	3
Constant	2.038*** (.401)	3.32*** (.539)	2.697*** (.676)
Control variables			
Party competitiveness	-5.153*** (.709)	-5.593*** (.659)	-6.072*** (.728)
Population density (logged)	-0.006 (.011)	-0.028*** (.009)	-0.027** (.011)
Median income (thousands)	0.011** (.005)	—	0.002 (.006)
Median education	0.094** (.031)	—	0.055 (.037)
Structural variables			
Income inequality	—	-0.292 (.319)	-0.485 (.354)
Educational inequality	—	-5.031*** (.551)	-4.003*** (.929)
Industrial heterogeneity	—	1.615*** (.448)	1.595*** (.457)
Ethnic heterogeneity	—	0.769*** (.148)	0.749*** (.149)
R^2	0.593	0.744	0.755
Adjusted R^2	0.565	0.717	0.719
(n=63)			

[a] Standard errors are in parenthesis.

Joint significance of structural variables

	1	2	3
	—	F = 23.68	F = 10.41
	—	df = 4/56	df = 4/54
	—	$p < .01$	$p < .01$

* $p < .10$ ** $p < .05$ *** $p < .01$

This variable takes on close to a normal distribution with a slight positive skew. The mean is 1.016 with a standard deviation of .274. The median value is .990.

7. As is always the case, the variables used in this analysis do not exhaust the supply of potentially interesting or informative variables. I have chosen variables that capture the extent of differentiation on basic parameters such as ethnicity, occupation, income, and education, that have been shown in the past salient in the formation of political interests. An obvious omission is a variable measuring religious heterogeneity. Undoubtedly, religion plays a role in many of the social issues included in this study. The omission of a religion variable is not necessarily fatal, however, since religiosity and religious preference are associated, to a great extent, with variables reflecting ethnicity, education, income, and occupation. One might conceive of religion as being an intervening variable in this case. Nevertheless, if county level data on religiosity or religious preference were available, it would be a valuable addition.

8. I also employed a random effects model. The results (not shown) were not substantially different from the results of the fixed effects model.

9. The issue specific dummy variables, also do not seem to have an impact on the model. A test of the joint significance of the issue specific dummy variables, in all three models, yields an *F* value that is far from having statistical significance. Tests of the joint significance of the four structural variables, however, are significant.

10. As a check on these findings I also run the analysis without utilizing a panel design. Instead, I simply take the counties' mean score on the dependent variable across the eight initiatives and regress that on the independent variables. In this approach, the signs of the coefficients are the same as in the pooled model. The sizes of the coefficients are also very close to those of the pooled model. Income inequality is not statistically significant, while the coefficients for educational inequality, ethnic heterogeneity, and industrial heterogeneity are highly significant and in the expected directions. Since the effects of the independent variables are much stronger on some of the issues than on others, aggregating the dependent variable, as opposed to using a pooled model, substantially increases the R^2. Nearly 76% of the variation in proactive voting is explained by the full model. The results of the aggregate models are reported in Appendix B.

11. Each structural variable is added one at a time, beginning with ethnic heterogeneity, and then followed by income inequality and industrial heterogeneity. I add educational inequality last since it is highly correlated with median education and with ethnic heterogeneity. It is interesting to note that in almost every instance, the addition of an inequality variable increases the coefficients of the heterogeneity variables in the model. In the same manner, the addition of a heterogeneity variable reduces the coefficient for the inequality variable. Ethnic heterogeneity enters the basic model negative and statistically significant on the 1980 lottery vote, and negative and of borderline significance for the 1988 abortion vote. In the first case the coefficient becomes positive and statistically insignificant when educational inequality is added. For the 1988 abortion vote, ethnic heterogeneity is no longer significant when income inequality is added. For the environment vote and for bilingualism, ethnic heterogeneity enters the model positive and highly significant and remains so with the addition of each structural variable. For the alcohol vote, ethnic heterogeneity becomes and remains positive and significant when income inequality is added to the model. For the 1988 gambling vote, ethnic heterogeneity only becomes positive when educational inequality is added. It is also interesting that when educational inequality is not included in the model, the partial coefficient for income inequality has at least borderline significance for the 1980 lottery vote, the 1982 alcohol vote, the 1984 abortion vote, the 1988 abortion vote, and 1990 gambling vote. When educational inequality is included, income inequality is significant only for the 1984 abortion vote and the 1990 gambling vote.

Insult and Inclusion: The Term *Fag Hag* and Gay Male "Community"*

DAWNE MOON, *University of Chicago*

Abstract

The term fag hag *is normally used in gay male culture to describe a straight woman who associates with gay men. This article uses intensive interviews with gay and bisexual men to explore what the term indicates about contradictions emerging from dominant views of gender and sexual identity. Other sociological studies provide explanations for why women and gay men form relationships and how these relationships are negotiated. This article explores what the term, residing at the nexus of discourses of sexuality and gender, tells us about (1) how dominant, heterosexual culture's assumptions threaten gay identity and culture; (2) the tensions present within gay male culture's own dominant discourses, tensions which certain straight women create and/or highlight; and (3) the limitations imposed on political mobilization by a discourse that posits the existence of a coherent "gay community."*

fag-hag: heterosexual woman extensively in the company of gay men. Fag-hags fall into no single category: some are plain Janes who prefer the honest affection of homoerotic boy friends; others are on a determined crusade to show gay boys that normal coitus is not to be overlooked. A few are simply women in love with homosexual men; others determine to their chagrin that their male friends are charming but not interested sexually. No matter how you cut it, fag-hag has an ugly ring to it. Syn: faggot-chaser (*pej*). *The Queen's Vernacular: A Gay Lexicon* (Rodgers 1972).

Interviewer: What are fag hags?
Billy:[1] Women, straight women, that hang out and run around with gay men. Some of whom I've known to sexually seduce gay men. That "one-good-woman" concept. . . . Also . . . one of my sisters used to run around with us and hang out. 'Cause we were fun, we did good drugs, we always danced, you know, and, but I never considered her a fag hag. She was not *interested* in dating any of my friends, so that's why I make the distinction.

* *Special thanks are due to Andrew Abbott, Julie Brines, George Steinmetz, and the reviewers of this journal, whose comments have been most helpful, and to the numerous friends and colleagues who assisted me with various versions of this article. Most importantly, I give thanks to the many respondents whose insights were both fascinating and crucial. Direct correspondence to Dawne Moon, the Department of Sociology, 1126 East 59th St., University of Chicago, Chicago, IL 60637.*

 Social Forces, December 1995, 74(2):487-510

Interviewer: What do you think makes someone a fag hag?
Henry: [They are] women who choose to participate with homosexual men, not lesbians so much, because they relate best to them, they don't relate well to other women maybe, and not to straight men either, it's just, that's the group they relate best to.

Darren: "What *makes* them be that way?" this is a topic from, for you know, for the Montel Williams show, or . . . "What *makes* women want to *associate* with gay men?" I think an open-minded liberal attitude, so not being hung up, on sexuality to begin with, um, having met and had a positive relationship with someone who is gay or lesbian, so that you are not afraid that they're abnormal or perverse people and they're just normal people.

Interviewer: What does it mean, to the person referred to, to be called a fag hag?
Dean: It's a derogatory statement, in my experience, anyway. It means a masculine bitch, with a very big mouth, who will flaunt her relationships in public by acting like "one of the guys," making "cock-sucking" remarks or whatever — pardon the expression, and by bringing up your personal life whether you want her to or not. It connotes insincerity on their end of the friendship, and yours.

The term *fag hag* comes from gay male culture in the U.S.; while participants in this culture differ in opinion on to whom exactly the term applies and when, if ever, it is appropriate, it clearly denotes a woman, usually a straight woman, who associates either exclusively or mostly with gay men.[2] Gay men may use the term to refer to women who are friends and confidantes; they may see fag hags as "pathetic," as especially "together," or simply as women who happen to have gay men as friends. Traditionally, the term is an insult, yet it may be used in such a way that no offense is meant or taken. Why does gay male culture include such a term for certain women? What does this term, residing at the nexus of gender and sexuality, tell us?

I explore what leads some participants in gay male culture to use the term, and furthermore, why those who use it do so in such varied contexts. The term hints at how gay men, and other participants in their culture, perceive the women who enter gay "space," and how those perceptions change.[3] It calls attention to the strengths and limitations of "community" as a rhetorical strategy for a movement for gay/lesbian/bisexual/transgender liberation. Furthermore, it highlights areas of conflict within popular gay male definitions of "who we are," conflicts that arise from the various ways people reconcile the contradictions inherited from dominant discourses of gender and sexuality.

To learn about gay men's experiences with the term *fag hag,* I used a snowball sample and an intensive interview format covering 33 men who identified themselves as gay or bisexual and who were familiar with the term. Interviews took between a half hour and two and a half hours. Respondents ranged in age from 17 to 68, exhibiting a broad range of qualities within gay culture. They varied in the degree to which they considered themselves "out," or openly gay, and also in levels of involvement in gay cultural and political activities. Furthermore, they varied widely with regard to their opinions on the definition and propriety of the term *fag hag,* as well as in how often, if ever, they used the term.

While it is a strength of the interview method of data collection that we can get at people's experiences and use them to test both theories and popular rhetoric, "experience" itself is shaped by rhetoric and ideology, as Scott (1992) so convincingly points out. As she asserts, what rhetoric and world views predominate will indeed affect how people experience gender, sexual identity, and relations among people in different categories along these axes. Thus, as people's experiences vary, so will their criteria for judging whom they consider to *belong* in gay space. Indeed, the boundaries of gay space are a site of constant redefinition, and these definitions are influenced by the various points of tension within gay male culture. The term *fag hag* resides at the boundary between who belongs in gay space and who does not, highlighting the tensions within a discourse of gay identity, tensions related to people's experiences of community, gender, and sexuality.

By exploring these issues, we can further understand the dynamics of heterosexism and sexism and how these dynamics are supported or subverted. As I will discuss further, gay male culture consists of multiple discourses of gender and sexual identity. Participants in this culture create it in an ongoing process, and they do so coming from diverse places and eras, bringing with them a variety of experiences and understandings of their world. Thus, on different occasions different tensions emerge as salient and terms such as *fag hag* come to have a variety of meanings.

It is important to set up some working definitions of terms. I use *straight* to refer to persons who identify themselves as heterosexual. What I call *heterosexual culture* dominates most U.S. cultures; it consists of the set of ways in which people's sexuality is limited by usually unquestioned assumptions (at times backed up by outright coercion) that sexual attraction is only "natural" if it occurs, along with other limitations, within certain social groups and across genders. Because heterosexuality structures the dominant culture, constantly being made to seem both natural and universal, it could be described as a hegemonic order, retaining a position of apparently total social authority in spite of everyday resistance.[4] The term *fag hag* parodies that order, at times subverting and at times reproducing it.[5] That "fag hags" exist suggests that even though most natives of the U.S. were and are raised in heterosexual culture, not everyone who is straight leaves all its fundamental assumptions unquestioned, and not everyone who is not straight questions all these assumptions.

I use *gay* to describe men who identify themselves as such and who participate in "gay [male] culture." "Gay culture" refers to the common system of gay language, history, and pastimes shared by those who identify as such. These people may or may not consider themselves "homosexual," since bisexuals and others who do not conform to the dominant model of heterosexuality may also at times be seen as insiders.[6] As a subculture in U.S. society, gay male culture is defined from both inside and outside, in relation to and in opposition to, heterosexual culture's model of "natural" sexual and gender relations. Within that culture, however, participants bring numerous overlapping and competing understandings of gender and sexuality. The culture is always affected by dominant discourses, and as different understandings of what it is to be gay develop, tensions emerge within gay male culture. These

tensions are at times highlighted and at times created by both the term *fag hag* and by those to whom it refers.

In the U.S., gay men and lesbians have determined continually the boundaries of their space vis-à-vis the dominant culture in order to communicate among themselves while protecting themselves and each other from persecution (e.g., Chauncey 1994; D'Emilio 1983; Goodwin 1989; Kennedy & Davis 1993). In recent decades, however, much weight has been given to the concept of "the gay community." Among both insiders and outsiders, gay community is a notion often used to describe a politically mobilizable, clearly defined group formed around members' perceived shared interests. These interests are supposed to emerge from members' common experience of being gay.

As I will discuss further below, the term *gay community* is ambiguous and problematic. Patton (1993) illustrates that the rhetoric of community and its related politics of identity evoke a sense of duty to a cause. While the term's ambiguity lends it rhetorical strength as a device for mobilizing political constituents who share certain sexual identities, it also masks existing inequalities that can lead to disunion among those it is supposed to unify. Furthermore, a notion of gay community rests on the assumption that being gay entails sharing compatible political interests with others who are gay, while positing that "gay" people's interests always oppose the interests of those who are not gay. At the end of the article, I make it clear that the existence of straight women who associate with gay men and who participate in gay cultural pastimes poses a problem for such a conception of community.

This article starts by examining respondents' views of women and the term *fag hag*. I discuss the more traditional use of the term as an insult, placing the term and the women it represents in the context of gay culture's ongoing process of self-definition. I then move on to explore ways in which the term is interpreted not as pejorative, and explore possible reasons that the term remains ambiguous. Finally, I examine what the existence of fag hags suggests for students of political mobilization, specifically for those interested in the politics of sexual liberation.

Tensions within Gay Male Culture

How a speaker conceives of or perceives "the gay community" affects how he or she defines the term *fag hag*. In fact, as a term that denotes "otherness" in the fields of both gender and sexuality, *fag hag* appears at points of tension within the ongoing discourse of what *being* a gay man means to gay men themselves. As with other identities, people sharing a gay identity look for things they have in common, yet sometimes they reach different answers to those questions.[7] In general, men who ally themselves with gay culture see themselves as in some way opposing heterosexist domination. What exactly that rejection entails, however, and therefore what it *means* to *be* a gay man, vary as widely as people's experiences of gender and sexuality vary.

People's experiences and understandings of sex and gender vary, and furthermore, as I mention earlier, their personal experiences are both shaped

and understood through varying rhetorics and ideologies of sex and gender. Because of these differences, points of contestation emerge within gay cultures as to what it means to be gay and to reject heterosexist domination. These points of contestation include: (1) Given that heterosexist ideology would have all men love only women, can a gay man resist heterosexism and still love (or even like) women? (2) Given that the dominant culture often seeks to limit people's sexual freedom by prescribing when, how, and with whom an individual should have sex, does rejecting that dominant culture mean that gay men should be limited from having "heterosexual" relations? (3) Although people retain certain privileges when they do not reject heterosexuality, should gay men get these privileges despite opposing heterosexist domination, or should they reject the very existence of these privileges? How these questions are resolved at a given moment will be reflected in who is perceived as an outsider and how that outsider is treated. Therefore, *fag hag,* taken to denote "a woman who associates with gay men," varies in connotation depending on what it means to be a woman among gay men in different situations.

As I examine uses of *fag hag* among respondents, I consider salient issues within gay culture. I begin by looking at some examples of past uses of the term *fag hag,* suggesting where gay discourse derives some of today's major themes. I then dwell a bit longer on what the term can mean contemporarily. I take observations of uses of the term from respondents who participated in gay cultures from the 1940s through the 1970s. People who came of age in the same period share definitions of *fag hag,* and the interviews suggest that certain issues dominated at these times and shaped the dominant perceptions and issues that persist to this day.

Of the four respondents older than 50 that I interviewed, three were involved in gay culture to some extent through the 1940s, 1950s, and/or 1960s. In this period, the meaning of being gay changed greatly, but it was a period in which gay culture could overall be described as underground, where language and pastimes developed as ways for people to protect themselves and each other from persecution. Thus, "the gay world" came into contact with few outsiders of any kind (e.g., Bérubé 1990; Chauncey 1994; D'Emilio 1983; Kennedy & Davis 1993).[8] Fag hags existed, however, and opinions of them reflected the tensions prominent at the time.

Respondents whose participation in gay culture began in the 1940s or early 1950s define fag hags as "lonely" women who, for whatever reason, are outsiders to the heterosexual world.

Interviewer: What do you think makes someone a fag hag?
Lyndon: Some loneliness, a need to be accepted, and if a gay group accepts her, that's important. . . . I conceive a fag hag as a woman who enjoys hanging around gay people to the extent that she almost ignores heterosexual society. A woman who is lonely, who has no boyfriend but would like one and who uses gay society as a substitute.

Interviewer: Is any woman that associates primarily with gay men a fag hag?
Karl: I suppose not necessarily, but one who doesn't seem to have much interest in straight men, who may have some unresolved sexual conflicts in her life. Anyway she gets more attention from the gay men than she would from the straights; she seems to prefer their company. I suppose theoretically there could be somebody out there, in fact I know a woman to whom I'm out to. And she has lots of gay friends but she's not, I

wouldn't call her a fag hag in any sense of the word because she also has many nongay friends and she doesn't derive all of her strokes or social benefits from associating with gay men.

Like younger respondents, older respondents see the term as referring to "fat" and/or "unattractive" women, who stereotypically "can't get a date" — women who somehow *fail* to perpetuate the sexist, heterosexual ideal. These women may be "friends," "confidantes," and "mother figures," but they are also often seen as women who, like gay men, have been rejected from or have rejected the heterosexual mainstream. Indeed, in some instances, mainstream culture's rejection of these women is mirrored by this particular use of *fag hag*. This view carries over into today, as is clear from these respondents' opinions of the term's meaning and of the people.

In the 1970s, after Stonewall, gay men and lesbians made their cultures more visible to the mainstream than they had been previously, while focusing their political aims toward sexual liberation. During this time, even as some of the attitudes of earlier decades no doubt persisted, new issues emerged as well. One example has to do with the very visibility that the gay liberation movement was trying to secure. While coming out of the closet, or making gay identities visible, was a central focus of the gay liberation movement, such visibility also encouraged heterosexual "tourism" into gay venues. As Billy remarks:

Um, I would guess [the term] grew out of the, as the gay community grew as a bigger and bigger subculture, before the late '60s when people really started coming above ground as a gay community. I think it was one of those derogatory terms that set people apart, you know, and it may have evolved due to infiltrators. Infiltrators being straight folks that hang around in gay bars because they're perceived to be more fun. Um, it wasn't as big a deal to me in the '80s as it was in the '70s, but in the '70s I would be pissed, if a straight couple came into a gay bar, I, I would want them to leave. Because I would, I always had that feeling of "you have the whole world, I have this crummy bar, get out!"

At the same time however, this respondent discusses a woman who associated with him and his friends in the mid-1970s, saying she was *not* a fag hag:

I also knew, one of my sisters used to run around with us and hang out. 'Cause we were fun, we did good drugs, we always danced, you know, and, but I never considered her a fag hag. She was not *interested* in dating any of my friends, so that's why I make the distinction.

Harold, who came out later in the 1970s, remarks:

Well, I think ["fag hag"] is a rather unflattering term but one does have to wonder, if this person's entire social life is hanging out with gay men, um, it's as if they don't want a personal life or something, because they're certainly not going to end up in a sexual relationship with any of the men, oh, I would not be surprised to know that some would be interested in the possibility of it, but, I wish I had known some well so I could get a better sense of how to answer these questions. I'm kind of making guesses. Well, I want to emphasize that to me it doesn't sound like a very flattering term, and I guess I don't understand why a fag hag would want to hang around with gay men.

Indeed, a good number of respondents who were active in gay culture in the 1970s refer to "fag hags" as women who want to date gay men or who are "*too* interested" in gay men, women who sexualize their relationships with gay men.

These respondents' comments highlight two themes that seem to have emerged in the 1970s and that have carried through to today. On the one hand, as Billy's description makes clear, is the concern that a fag hag does not belong; she is like the straight "infiltrators" he describes. On the other hand, both Billy and Harold, like numerous other respondents, define *fag hags* as women who want to *date* gay men, therefore rejecting the men's identities as gay. A few respondents see this as the "one good woman" concept, where a woman thinks she can "convert" a gay man. It would not be surprising if the threat of "conversion" became salient in response to the gender and sexual liberation discourse of the 1970s, which stressed social constructionism and suggested that sexuality was not biologically predetermined, but constructed and fluid. Both of these tendencies emerge in the sample when it is considered as a whole.

Having briefly periodized some themes within gay male culture, I now turn to the sample as a whole and look at what it says about respondents' attitudes about the term *fag hag* today. The themes described above carry on, and contribute to, debates within discourses on gender, sexual identity, and community within gay male culture. I first look at tensions highlighted when the term is used in its traditional way, as an insult. Then I look at contexts in which the term is used in an inverted, joking, or neutral way among close friends.

Tensions in Gay Culture and Insulting Uses of *Fag Hag*

REJECTION OF WOMEN VERSUS REJECTION OF HETEROSEXISM

As suggested in the introduction, gay men may perceive themselves at odds with heterosexual culture, possibly even seeing themselves as rejected by it. Several respondents comment that using the term *fag hag* relates to some gay men's "self-hatred" or "insecurity" about being gay. These problems may be expected, as people who defy heterosexual norms are often categorized as "sick" or "unnatural" and face threats of violence, discrimination, and ostracism. The discourses of heterosexism and sexism may put a gay man at a certain conflict, that between (1) a gay-affirming rejection of the heterosexist structure that would have all men love women, and (2) a sexist rejection of women.[9]

At some moments, gay men see a woman's gender as setting her apart from her gay male surroundings. There are instances where gay men's rejection of heterosexual culture can verge on rejecting *women*, perpetuating the dominant culture's sexist attitudes, even while such men share women's oppression under conventional heterosexual ideology. Some men may not disguise their sexism with an excuse of rejecting heterosexism. As two respondents comment:

Interviewer: Are some people more likely than other people to call someone a "fag hag"?
Harold: My guess is that gay men who aren't overly fond of women probably would be more likely to use that term.

Interviewer: Are some people more likely than other people to use the term?

Karl: I'm really not sure, you know, I, I could imagine there would be but I couldn't identify them. I suppose it shows a certain degree of hostility. I suppose some people who are more hostile towards women might be more inclined to use that term, more than others.

Another respondent attributes such negative feelings towards women to some gay men's own self-hatred, as Terry says:

it's used, in my opinion, as a clear expression of self-hate, that is to say, that gays who dislike themselves are projecting that dislike of themselves onto someone who is friendly to them. I think that is why I dislike this term so intensely. For me it is a reflection of a sort of confusion about identity and a confusion about the value of one's own identity.

At one level, then, men may use the term *fag hag* to insult women; a number of respondents see men who use the term in this way as "insecure" or "self-hating," feeling rejected by mainstream society on account of their homosexuality. At times, rebuking heterosexism can verge on rebuking women; at other times, it seems, the term most certainly indicates a case of misogyny where a woman is scorned both by heterosexual society and by gay men.

Yet to write off all use of the term *fag hag* as self-hating or sexist would blind us to many of the intricacies of gay male cultures. At times, men who do not consider themselves self-hating use the term to sanction certain women who do not seem to support gay culture's norms or the gay identities of those around them. At other times, the term will sanction certain men who seem to blur the boundaries of gay space. And at other times, the term will be used symbolically to include women as part of a group of gay men. I discuss the term's inclusive uses below, but first I examine uses of the term *fag hag* as an insult that need not betray direct sexism on the part of the speaker.

SEXUAL FREEDOM VERSUS GAY COMMUNITY

There is a nonmisogynist way in which being a woman constitutes a threat to gay male identity. This threat comes in part from a dialogue between two discourses: (1) a discourse of sexuality as a malleable construct, and (2) a discourse of gay community building as a route to political empowerment. Does challenging heterosexism imply that gay men must be forbidden from having "heterosexual" encounters? What "duties" does identifying oneself as gay include? Before addressing the possible conflict between two discourses, it is important to consider how some respondents see fag hags as a threat to gay male identity and to a sense of gay male community.

To many respondents, the most obvious use of *fag hag* describes women whose overt behavior makes them appear not to accept their gay male companions' sexuality. Several respondents see these women as a "problem." These women actively draw notice to the problem inherent in a discourse of sexual malleability. For instance, as noted above, fag hags are associated by many respondents with sexual tension or unrequited love relationships. For some, these relationships define a *fag hag* and without them, one is something else, if labeled at all: a friend or acquaintance, for instance. In cases where overt behavior elicits use of *fag hag*, the term is used as a sanctioning device to reject women who may represent heterosexist views of gender and sexuality.

Respondents recall a number of threatening behaviors that women have used around them. Fred recalls a woman who went to the extent of proposing marriage to him, and Oliver discusses a woman he and his bar friends associated with, who would habitually drink too much and proclaim her love for one of the men of the group, crying and saying "But don't you understand? I really love you." Numerous others mention women "falling in love," "wanting to date," or "promot[ing] sexual tension with gay men." Furthermore, to call such a woman a "fag hag" may mean that she vicariously "lives off of" her gay male friends, or has "no life of her own."

A good number of respondents remark upon the sadness of these situations, but a number make it apparent — whether with descriptions such as "inappropriate" or "setting themselves up to fail," or with the love object's ensuing response of "get off me!" — that these situations are awkward for both parties in question. It is difficult not only for the woman for whom "all the good guys are gay," but for the man as well, since these situations manifest the woman's lack of acceptance of the man's self-identification as gay. To these respondents, a fag hag does not understand or accept what it means to be gay; these women refuse to understand the respondents' belief that a gay man could never have any sexual or love interest in a woman.

Heterosexist common sense dictates that people may not love or have sex with whomever they want, but does challenging such domination allow for the possibility that a gay man might sleep with or fall in love with a woman? For some respondents, *fag hag* seems to refer to a woman who encourages such a transgression of the gay/straight binarism. However, some find even more threatening the possibility that a "gay" man *could* have such an interest in a woman. This threat resides at the nexus of tension between the ideal of sexual freedom and that of gay community. In the community model of gay liberation, it is often implied that gay men have a duty to act as unambiguously gay as possible (Rubin [1984] 1993). While gay community building rests on the construction of stable gay identities, the pursuit of sexual liberation is founded on a rejection of such stable identity formation.[10]

Some respondents, apparently influenced by the community-building logic, see the women they consider to be fag hags as threatening in their apparent disrespect for the norms of gay male culture; others, caught in the irony between the two logics, do not consider the term to apply only to a certain kind of women, but to any woman in gay space. That any women among gay men may be considered conspicuous or threatening calls attention to a problem emergent from the contemporary discourse of "gay community" — even if it strives for a goal of individuals' sexual freedom, it risks perpetuating the logic that there are "naturally" two complementary sexes, a logic that can neither explain nor accept experiences that escape this divide.

Women's threat within gay culture comes from this dominant binary logic as it continues into gay male discourse. The threat women can pose becomes obvious when we reflect that straight or "straight-acting" men who participate in gay culture do not have any widely used special label. One of the respondents discusses this disparity and suggests that "straight" men who associate with gay men are more likely to be considered "closeted," gay but not yet open about it. While a person may be referred to as *closeted,* this term is used less

frequently than *fag hag* as a direct insult. Since almost all gay men have to some extent identified themselves as straight before taking on a gay identity, this identity poses a less salient threat in gay culture than that posed by straight women in certain contexts.

To suggest that simply *being* a woman constitutes a threat may sound far-fetched, but the prevalent view that heterosexuality alone is natural endangers an individual's maintenance of a gay identity. When a gay man associates with a woman, even if he does not wish to hide his gay identity, many people would presume him to be straight unless he "acted" gay. This is so because heterosexual culture appears to inundate many aspects of life, from the media to the family to the legal system. From the perspective of someone who does not identify with the heterosexual mainstream, it appears that when a man and a woman are seen together the mainstream assumes that they are heterosexual; they do not challenge that dominant view of gender relations.[11] Thus, for a gay man to reject women's presence in gay space may be an attempt to challenge heterosexism, albeit one that seems short-sighted in the logic of sexual liberation.

One respondent provides an illustrative example. Steve describes a confrontational situation, in a gay bar, for instance, where one gay man approaches another who enters with a woman, snaps his fingers in the direction of the woman and asks the man, "Who's your *fag hag?!*" In such an instance, the speaker reminds the addressee that the woman is a fag hag, and therefore the addressee *is a fag*. Certainly the rudeness and sexist implications of pointedly ignoring a woman in such a situation cannot be denied, but this scenario also points to deeper issues and supports what postmodern theorists have articulated, that sexual identities are not only socially constructed but also tenuous (Butler 1993).

That the speaker may feel the need to remind a man of his supposed sexual identity suggests that the discourses of sexual identity and liberation conflict at times. In this gesture, the speaker seems to be calling attention to the potential for a sexual relationship between the fag and the hag, a situation that could be seen as betraying "the community." Indeed, by providing a model of what a man must do in order for other gay men to consider him gay, a discourse of gay identity limits acceptable behavior in ways that limit personal freedom. In this case, it limits with whom a man may associate if he wishes to go to a bar without being bothered.

If a man associates with a woman, he may look straight, but if he goes to a gay bar with her, and appears to want to be part of gay culture, he may be viewed as a marginal participant, one who has an ambiguous relation to gay culture. A participant in gay culture may call the accompanying woman a "fag hag" even if she does not actively question the value of being gay; in such a case, the term is used in reference to the woman, but to sanction the man. In a discourse of sexuality as a malleable construct, the tension arises between the desire for sexual liberation, on one hand, and the fear of gay men straying beyond the boundaries of "the gay community," potentially weakening it, on the other. This threat to the gay community's stability comes from the paradox that sexual liberation need not require a man to behave exclusively "gay," in the definition created by the dominant voice in gay culture.

HETERO-PRIVILEGE VERSUS GAY COMMUNITY: FAG HAGS AND MARGINAL MEN IN GAY SPACE

When respondents talk about fag hags in relation to marginal men in the gay scene, it becomes even clearer what kinds of symbolic threats are salient within this culture. Marginal participants in gay culture bring me to a third tension in gay discourse, this one also related to the rhetoric of gay community. Respondents see as marginal those men who appear less secure with a gay identity. These men, usually younger or "newly" gay, bring with them to the threshold of the gay world their straight female companions. Unacculturated to the ways of gay male culture, these individuals behave in ways the people around them deem inappropriate. Such behavior hits on the conflict between wanting to become a part of a community of gay people and wanting to retain the privileges that come from membership in the heterosexual mainstream. Does rejecting heterosexist domination imply taking heterosexual privileges in spite of being gay, or does it imply rejecting the very existence of these privileges?

This segment of gay life is pointed out in the data by about a quarter of the respondents, who associate the presence of fag hags with youth and insecurity about one's sexual identity. Martin points out the insecurity he ascribes to gay men who associate with fag hags:

> Others might perceive my friends as fag hags, but I don't. We don't put on the air that we're heterosexual. Sometimes in a bar, a gay man will be acting like they're in a heterosexual couple, where he'll just be spending all of his time with the woman. That's kind of a crutch, dealing with [internalized] homophobia. . . . Also some people feel uncomfortable with two men dancing together, even in a gay bar, so she's kind of a buffer. . . . I've used it negatively too. If someone is having a hard time coming out, and is playing games with people and not being honest, I'll be like, "Oh there's bla bla bla, with his fag hag, fooling the world." [If the other man is trying to pass as straight.] But that's my own self righteousness, but I feel angry at that injustice against the gay community.

The presence of a fag hag indicates insecurity on the part of the man who has her around. Martin suggests later in the interview that he has noticed it among younger gay men, of high school or college age, also perhaps indicating insecurity, if we assume people tend to be less insecure as they age. This "insecurity" differs from Terry's description cited above, where he sees men who use the term *fag hag* as indicating disbelief that a straight person would want to associate with gay men. In the case described by Martin, the man with the fag hag is not fully self-identified as gay; this weak gay identity makes it unlikely that he will participate in gay activities, and makes him wish to buffer himself from other gay men by associating with a woman.

Another respondent, Steve, describes associating with fag hags as "an adolescent phenomenon," and later continues:

> I would expect to hear it in a college dormitory, or in a nightclub . . . because it's a term used by, um, more, like, freshmen, late adolescents. . . . It's more like, a need for protection, 'cause I think it's often the relationship between the fag and the fag hag was one of self-defense. 'Cause the fag hag doesn't want to be pegged out as a single woman who doesn't have a date, and the fag doesn't want to be pointed out *as a fag*.

And Oliver explains:

She was some sort of weird — I'm thinking of [a particular woman] now — she was always some sort of strange buffer between ourselves and, that bar scene which was pretty nasty, where I was hanging out. (chuckle) . . . And I'll see it, nowadays, I'll see, and they seem like they're seventeen years old, and they got some sort of fake ID going, and they're just really silly . . . It's some sort of weird stage, for both of them.
Interviewer: What kind of stage?
Oliver: A stage in terms of, until both of them get acclimated to what sort of realm they want to function in. Like that gay man, that boy, wants to be in the gay community, and the gay bar scene in specific. This stage about getting to, where you can walk in there alone. You can't do that when you're seventeen.

These respondents, all speaking from personal experience, see a fag hag as someone a young, unacculturated gay man will cling to as a buffer between himself and the gay world. By "clinging" to a woman, the man keeps from appearing gay. If the woman is seen as the object of hostility, she will be derided as a "fag hag," as we saw with Martin's commentary at the beginning of this section. Both Steve and Oliver illustrate the relationship as one of mutual defense between the young man and the woman, where the man fears being overwhelmed by gay culture, and where the woman, for whatever reason, seems insecure, or afraid of being pegged as "a woman without a date," who fails to live by heterosexual standards. While the man may or may not be likewise derided with his own pejorative term — like *closet case* — the woman may receive the label of *fag hag*. In such cases, she is derided for her friend's insecurity. If her male friend is not fully an "insider," her own presence becomes salient and threatening. As the next section will show, if a man is an insider to gay male culture, a female friend of his may be an insider also.

As an unacculturated gay man "clings" to a straight female companion, as we have seen, he buffers himself from "the gay community." Thus, another tension within gay culture is visible in Martin's commentary. In his view ("I feel angry at that injustice against the gay community") the gay community is a collective to which a gay man has a duty to reject the comforts associated with being presumed heterosexual. This sense of duty echoes that discussed by Patton and that I discussed briefly above. Since Stonewall, this duty has been constructed through a discourse of unity and liberation. This discourse has created a conflict, however, for even as coming out has been framed as part of one's duty to *the* gay community, coming out has also been framed as a route to an individual's *personal* fulfillment. From these potentially contradictory discourses, the age-old tension between personal fulfillment and duty to community may emerge.

SUMMARY: INSULT AND NOT BELONGING

A good portion of respondents agree that it is not gender, but behavior, that makes someone deserve the label *fag hag* as a mark of opprobrium. As the above commentary from Billy suggested, a few point out that a woman gets called a "fag hag" if she is conspicuous, if she appears not to belong. This "sticking out" may be because she does not appear to accept her companions' identities as gay, or it may be because her presence as a woman challenges the

dominant gender dichotomy as it applies in gay male culture. One respondent even takes the issue of belonging a step further, remarking that even a gay man can feel like a fag hag:

Oliver: Sometimes I used to consider myself, *my* self, a fag hag.
Interviewer: What do you mean?
Oliver: In that, I used to wonder, "What am I doing here?" Um, in that I can imagine [a certain fag hag we used to hang out with in the bar] asking herself, "What am I doing here?"

In this situation, the man was gay and is still gay, so it is not his self-identity that gave rise to the experience of discomfort, or not belonging. Rather, he did not feel that he belonged in the particular group with which he associated. Like this man, a woman might "belong," and feel that she belongs, more in some settings than in others. She would be called a "fag hag" where there was a question over whether she fully accepted the gay identity and culture of those in the group with which she associated.

As almost all respondents agree that not all women who associate with gay men are fag hags, a woman's presence among gay men can be perceived as threatening or not threatening at all. In some situations, an individual's gender is hardly an issue, whereas in other situations, a woman's gender does pose a threat. While respondents' definitions of the term vary, they converge to support the idea that women, because of their *being* women, cannot be assumed to be insiders. In gay male space women "stick out," as one respondent phrases it, yet in the words of another, women cannot be judged as fag hags "based on sight calls." Unlike gay men, women are not *assumed* to be part of the gay community, but must one at a time prove themselves worthy of membership. However, as many respondents make clear, it is not uncommon for women to be fully accepted as members of a particular gay community.

Determining the Perceived Threat: Group Cohesion

Since straight women often cause and highlight tensions in gay male discourse, a woman's behavior or even perceived identity may threaten elements of gay male community, hence she will be given a negative label in some instances. I have considered some contradicting themes in gay culture's ongoing discourse of self-definition, some of the norms of gay culture and some kinds of identities and behaviors within that context that may be perceived as threatening. What I have yet to examine is what, overall, accounts for the variation that exists in determining how threatening an individual will appear, whether the threat is symbolic or overt. To answer this question, we can explore the concept of how "cohesive" is a particular group of friends, strangers, or acquaintances, to what extent individuals are likely to conform to that group's norms, and to what extent group members share tacit assumptions about their surroundings.

In one model, *group cohesion* is defined by Homans ([1961] 1974) as the extent to which members of a group understand and accept common norms, follow them, and reward one another for "good behavior." According to Homans, in any group, members value conformity to the group's norms, yet because members are more similar and exchange more rewards in a highly

cohesive group than in a less cohesive one, it is less likely that a nonconformer will be present in a highly cohesive group. He gives two reasons for this likelihood: (1) because of the "tight-knittedness" of a more cohesive group, it is less likely that individuals who do not conform the group's norms will enter it, and (2) the few nonconformers who do enter will either quickly learn to conform or else will be driven out as a result of the strength of the disapproval earned by not conforming.

Many of the individuals in the sample suggest they belong to highly cohesive groups of friends. In cohesive groups, members all understand the group's norms and reproduce them. The tensions that arise in less cohesive settings, such as those examined above, do not exist in these more tightly knit groups. In a cohesive community, because group members know, trust, and support each other, their friends' gender or sexual identity is hardly an issue, and certainly not a threat. Thus, one respondent says that the straight women in his group of friends are a "nonissue"; they do not cause problems, nor does anyone expect that they would. They are accepted as full members of the group. Homans's idea that cohesive groups have widely understood norms, and therefore more reason to conform, finds support in this case.[12]

Fag hag is also used in certain kinds of cohesive groups as well, but Homans does not help us to understand why the term could be used in such a group. In these cases, the woman being addressed does not usually pose a threat, and when the term is used, it is in an ironic or joking way. Not all members of cohesive groups use the term in this "positive" way, however, so let us look further in to this area of the term's use.

Fag Hag: Some Take It "As a Compliment, Thank You"

If a woman is not fully accepted as a member of a group of gay men, she may hear herself being called a "fag hag." If she is accepted by others in the group, she may still be called a "fag hag," odd though this may seem. In this case, where the woman does not challenge her companions' gay identity, and where she is not perceived as a threat to the politically charged reproduction of a community of gay men, she may be accepted as a member of that community. Many of the respondents would not call this woman a "fag hag," since they see it as an insult, yet some would, and would do so without meaning it derisively. In these cases, the term's meaning is inverted to symbolically include these straight women in a group where, by some standards, they would not belong. Symbolically including women in a group of gay men can often be seen as rejecting not only the gay/straight dichotomy, but also refusing to participate in a sexist rejection of women.

Linguistic symbolic inversion, or using a largely pejorative term in an ironic, and empowering way, is an interesting though little explained phenomenon. This phenomenon has been discussed largely by scholars who studied African American slang in the early 1970s. Some scholars have argued that people may invert traditional insults, such as "nigger," "bitch," or "fag," in a way that makes clear the strength of the friendship between the speaker and the hearers, as insiders know whether or not to take offense (Abrahams 1976). One author,

Brown (1972), points out that for somebody who is a black "insider" to use the word nigger makes visible that that person *belongs* in a particular group of people.

Symbolic inversion also takes place in the context of gay culture. Gay folklorist Joseph P. Goodwin (1989) discusses this phenomenon:

> [Inversion] offers a means of insulting people who are so adept at stigmatizing gays, a way of expressing contempt that frequently passes unrecognized by those who have been insulted. Inversion also conveys a defiance of heterosexual standards as well. It is a way of saying to straights, "We do not accept your morality. We have our own culture with its own ethics, and these are the rules by which we live." (15)

As Hall (1982) also says, by reappropriating one of these terms in such a way, a speaker may feel personally empowered and furthermore, may contribute to a movement of ideological empowerment. As gay culture and gay politics have focused on transforming the social value of homosexuality and a gay identity, term inversion is not an unexpected phenomenon in gay culture.

Goodwin discusses inversion of terms that are normally pejorative. This reference applies to cases where gay men call other gay men names such as "fag" or "queer" as terms of affirmation or endearment where they would otherwise be seen as disempowering. A sizable majority of respondents in the sample point out that terms like these can be understood as joking or even endearing as long as they are used by another group member. As one respondent puts it:

> *Warren:* If anything, [fag] has become sort of a jocular term.
> *Interviewer:* In, uh, what sense?
> *Warren:* That it's a way to reassert to yourself the fact that you're okay. . . . My sexuality is certainly still an issue, and I still think about it a lot, but it's something that I have come to accept, and accept at such a basic level. . . . So, and by using the term fag on myself, it's just a jocular, joking sort of — you know, somebody else can sort of use that term to make fun of you, or to hate you, but, you know what it means [to be gay, whereas those who use these names to insult you don't understand that there's nothing wrong with being gay,] and it's okay.

As Warren and others indicate, these terms can actually strengthen the sense of camaraderie among participants in gay male culture when used in an atmosphere where tacit understandings are shared and the speaker's intention is clear. In a group of the type we have been discussing, a gay man who would not feel comfortable calling himself a fag, for whatever reason, would be quite unlikely to call a friend a "fag hag." Notably, a number of respondents who discuss the positive slant of inverting terms such as *fag* among friends and loved ones discuss such inversion as something that is acceptable "within *the community.*"

One may argue that inverting terms reproduces old prejudices while failing to create new meanings for these terms, yet such an argument places too much importance on words' ability to forever contain a set meaning. Words are made up and used by people, and slang terms, which are not usually learned with formally codified definitions, have meanings that may vary even more than most terms. Judging from the variety of responses in this sample, it appears that

people's own experiences have a great deal of influence on their definitions of the term *fag hag*.

The firm link between words and ideas has been greatly challenged by linguists and sociolinguists, and the work of Rommetveit (1974) is particularly useful for our purposes. Rommetveit indicates that in situations where people best understand each other, they require the fewest words to communicate. He gives the example of a man uttering to a woman the word "pot," a situation that would be meaningless to an outside observer, yet that would make perfect sense to someone who knew that the two were married, had a teenage son, were concerned about his unusual behavior, and understood the word "pot" as slang for the drug marijuana. To that observer, as to the woman in the situation, the husband's hypothesis about the son's drug use would be perfectly clear, because so much in the situation "goes without saying."

Of course, this example involves neither the use of an insult nor its symbolic inversion, but Rommetveit's ideas still elucidate our question. To an outside observer, the utterance "You fag!" could be interpreted with its conventional insulting meaning, yet a number of respondents recall situations where offense was not intended by another gay man making the remark. Consider two gay men who understand that they are old friends, that they are both gay and consider their orientations a blessing, and that one's wanting to play a Judy Garland record at a birthday party is a stereotypically gay activity and therefore a good one. In this situation, one gay man saying "You fag!" to the other may be seen as affirming and supportive so long as the two were confident in their agreement that enacting a gay stereotype was not bad behavior for gay men. Because stereotypically gay behavior is derided by much of the dominant culture, the utterance becomes a joke shared by those "in the know" against that derision.

A number of participants in the study draw a parallel between using terms like *fag* and *queer* among gay friends and using *fag hag* with close, straight female friends. This parallel does not quite come, however, since those using the term are not fag hags and those receiving it are not gay men. If it were two women in this situation calling each other fag hags in an endearing or ironic way, in a gesture of flouting their shared stigma, there would be a parallel, but this would be a different situation.[13]

More often, in situations where the term *fag hag* is used in an endearing way among friends, it appears that it is used by men symbolically to establish or affirm a woman's membership in the group of friends. If a gay man does not feel threatened by these women, he may view participation in gay pastimes and acceptance of a gay identity as more important than being a gay man per se. By using the term in such a way, a man may pull a female friend closer into the realm of insiders. Thus, as one respondent says, using the term can be seen as a gesture of affirmation, a way of saying, "You may not be gay, but you're a fag hag, so you're cool now." Another says calling a woman a "fag hag" is "kind of inviting a woman to share the stigma of being gay in our society." In such a use of the term, respondents make it clear that they see gender as a "nonissue," implying that they reject the sexism traditionally associated with the term.[14]

Not only can the term consciously be inverted to include women in the group, but its inclusive properties can also be less overt. A few respondents

point out that if the term is used in a situation among close friends, it is intended as a joke. It might be used in the context of making introductions, where the man making the introductions might introduce the woman with something to the effect of, "And this is our fag hag," with a wry look to convey the message, "but of course she's not really." Another joking situation that several respondents bring up is using the term to poke fun at a woman if she does something silly or slightly annoying.[15] Jokes, as Homans points out, can serve as a reward for positive social interaction. As members joke with an individual in this fashion, it seems reasonable to assume that they feel she belongs in the group. Furthermore, by sharing in such an inversion of the term, participants in the conversation share a joke against the dominant culture that would have this straight person shun gay men instead of befriending them.

People who use the term *fag hag* positively view the term as empowering for the gay community as a whole; they use it not to make an issue of the woman's behavior or sexual identity, but to reclaim the label for their own empowerment. Of course, in many instances where straight women succeed in being recognized as "members" of a group of gay men, or "gay friendly," they will not be called fag hags. In most of these cases, individuals do not see their friend's gender or sexual identity as noticeable or worthy of a label. Gender and sexual orientation are not, for these respondents, sites of tension.

Overlapping with the cases of those who do not use the term because they feel that a friend's sex and sexual identity are not problematic are those cases where the men do not feel comfortable inverting the term and using it in an ironic or joking way. One respondent says, "I am just not at the psychological stage where I can use those terms in that way." Why this would be may have to do with factors of sociological interest or may be largely due to such individuals' different backgrounds and factors beyond the scope of this study. This perspective does not appear to be uncommon, however, and should not be forgotten as contributing to the use of the term *fag hag*.

Within the arena of "positive" use of the term, we have seen that its inverted use will take place in more cohesive face-to-face groups, where the women do not pose a threat, but share in the tacit understandings of their group of friends. Gay men who, in this type of situation, would invert pejorative terms with reference to themselves, may use the term to express symbolically that these women are insiders of their community. Whether spoken or not, friends in these cohesive groups share the understanding that they resist the dominant sexual order by forming meaningful and rewarding relationships outside of the binary norms that would dictate that every sexual relationship occur between a man and a woman and that would not often allow for platonic relationships across the gender divide.

Among these respondents, symbolic inclusion is likely to be used among those who perceive manipulation of language as a route to personal and political empowerment. And although this sample is relatively small, within it those who fall into this category tended to be those more plugged into gay cultural activities and/or active in contemporary gay politics. Indeed, these men themselves could be defined as "more inside" than others. An individual seems to need a certain degree of familiarity with gay culture before he or she can play with its language. Just as one need not be a gay man to participate in gay

culture, one will not automatically be a member of that culture if one simply behaves in some way like a gay man.

One Term for Two Kinds: The Persistence of Ambiguity

As the above sections have illustrated, roughly two kinds of women involved in gay culture may be called "fag hags" — those who in some way challenge gay identity or the boundaries of a group, and those who affirm the value of being gay while challenging the limits of a strictly defined "gay culture" that would be threatened by a woman in gay space. These appear to be to radically opposed types of people indeed, yet no semantic difference exists to reflect this. It appears that the reason only one term exists, the negative, sanctioning term, is that only in a threatening context is a friend or acquaintance's gender or sexual identity salient.

The term has become more ambiguous as the value of a gay identity among nongays has become more ambiguous. Until recently, as some respondents comment, few heterosexuals had contact with groups of people who were gay or bisexual. But this situation seems to be changing. In recent decades, gay activists, commentators, and other gay leaders have stressed the importance of integration between the two sets of cultures and increased understanding (Marotta 1981). Perhaps intermingling among persons of varied orientations has blurred the boundaries that distinguish these different cultures. It has thus become more difficult for gay men to instantly discern who is a threat and who is a friend.

Because of the tenacity of gender and sexual identities, often a woman in a gay setting may be called a fag hag, as Dean puts it, "based on sight calls." Most of the men in the sample have friends who are straight women. But as Oliver's testimony suggests, even a woman who appears to accept her gay male friends' identities might one day break down and betray a lack of acceptance or understanding. Furthermore, the term *fag hag* remains ambiguous because different themes of gay culture predominate in different situations. Men with different pasts, who come out as gay or bisexual at different times in their lives, and who have different experiences with the women they do and do not consider fag hags resolve common tensions within gay culture in different ways.

A word will probably never exist to denote simply "straight female friend of a gay man," given that when a woman is threatening, her gender or sexual identity may become noteworthy. Numerous respondents make clear that they do not consider friends fag hags simply because they happen to be straight women. These women understand and accept that their friends are gay men but do not consider sexual identity as the only salient defining characteristic. Their shared understandings go beyond that level, and, regardless of outsiders' assumptions about the relationships between gay and straight people or between women and men, my respondents consider their friendships deep and meaningful.

As friends, gay men and straight women in cohesive settings may joke with each other about common outsider perceptions of their relationships. Such a joke may affirm the how close the friends are by affirming their common

understandings that have grown throughout their friendships. In addition, by using an ambiguous term the speaker may also highlight the difference between "insiders" and others. Only those sharing the speaker's underlying assumptions will understand the joke.

Because the term *fag hag* is loaded, respondents see it as a term "to be careful with." Its ambiguity will persist for quite some time. Because people interpret terms that comprise our ideas of gender and sexuality, as long as being "gay" persists as a concept similar to how it is understood today, gay men's identities will at times be threatened symbolically by being with women. Themes that emerge in one period are slow to die away, so such threats as those I examine here will undoubtedly persist. Only if gender and sexual orientation cease to be salient as structurally oppressive personal identities would such a threat disappear. What is clear from these interviews is that gay communities, and parts of the straight world as well, are broadening their boundaries as people who are gay and those who are not have come to share lasting and important relationships.

Problems for Community Mobilization

Gay political movements have used the rhetorics of identity and community to mobilize potential beneficiaries' sense of duty to their cause. However, the fact that gay men have female friends, whether or not they are called fag hags, sheds light on the problems that emerge from any strategy that seeks to build a movement based on the dominant culture's sexual categories. These problems emerge because these categories do not necessarily mirror how people view their own experiences. To the extent that these issues may intervene in the process of political mobilization, they merit attention.

First, post-Stonewall gay politics has popularized the belief that taking on a gay identity makes one belong in *the* community, and that it is the only way to belong. This dominant rhetoric of gay community reaffirms the notion that gay and straight people necessarily oppose each other. Such an opposition comes into question when we think about fag hags and their gay male friends. At times, gay men see fag hags and other women as part of their own community, even though by the dominant gay rhetoric, they would not belong in *the* gay community. If the straight-vs.-gay dichotomy finds support in a movement for sexual liberation, that movement may limit political mobilization by alienating those for whom that opposition does not mirror experience.[16] Indeed, this opposition could be said to alienate many of the people who seek alternatives to the dominant culture in the first place.

Post-Stonewall politics also bring out other issues that relate tangentially to the case of fag hags and that are largely related with the notions of belonging. The movement's heavy political investment in the existence of a unified gay community reifies the dominant culture's notion that people come in distinct sexual species with common interests. This "species view" of sexuality, critiqued by Rubin ([1984] 1993) itself creates two problems. First, based on the harmful dominant myth that species of people exist in nature and have distinct "natural" essences, this perspective undergirds a discourse that can harm people by

legitimating discrimination and violence.[17] As a number of authors point out, dominant categories of sexuality define groups that may then be persecuted directly by government and other institutions, while individuals who harm no one are often deprived of jobs, housing, their children, and personal safety by this persecution (i.e., Rubin [1984] 1993; Seidman 1993; Patton 1993). Therefore, a movement for sexual freedom does not aim only for unfettered sexual gratification, but for freedom from such persecution.[18]

Thus the dominant discourses of sexuality can have very concrete consequences that are legitimated in part by these discourses. The species discourse, for instance, serves this legitimating function — ironically as Sedgwick (1990) makes clear — since while it is based on the notion that different "kinds" of people exist in nature, it is based also on the contradictory belief that one kind is healthy and others pathological, or one kind is sacred and others sinful. Therefore, while a movement founded on a notion of sexual identity may prove useful for short-term mobilization, it seems that one based on a shared stake in sexual liberation has much larger pool of potential contributors, as it bears the potential to benefit people who do not fit cleanly into the dominant culture's categories as well as some who do.

While the rhetoric of sexual identity reifies oppressive categories, the rhetoric of community assumes that taking on a publicly gay identity gives people common interests, an assumption that proves to be false in light of the political diversity even in this small sample. Furthermore, supposing that all people who share a certain identity belong to a community masks inequalities *within* the movement's supposed constituency. The gay community is an *imagined* but nonetheless very consequential community, as Anderson (1983) characterizes nations: imagined, "as both inherently limited and sovereign." Anderson points out that the perceived "horizontality" of an imagined community at times masks existing inequalities among "members." In keeping with Anderson, Seidman (1993) points out that the notion of a gay community is invoked in spite of immense differences among its imagined constituents in terms of class, race, gender, region, cultural background, identification as gay, sexual preferences and object choice, personal style, and a host of other characteristics that often lead to inequality among supposed members. If face-to-face communities include gay men who do not behave ideally gay, other gay people in these groups may become alienated from a politics of mobilization that focuses on gay identity as a basis for community, thereby not reflecting people's experiences.[19]

At the same time, as Seidman shows, this strategy excludes potential supporters and constituents who have a stake in a politics of sexual freedom and civil rights protection. Like fag hags, other nongay people who differ from or disagree with the dominant culture's sexual norms — people who are bisexual, transgendered, asexual, or participate in S/M, for example — do not have a place in the gay/straight dichotomy. Excluding such people weakens political mobilizing by limiting the size of the political constituency as well as by reifying the harmful and erroneous gay/straight dichotomy.

Fag hags and their gay male friends live in opposition to the view that gay and straight people have radically divergent interests. These people may be alienated by a political agenda that pays too much heed to the dominant

culture's radical opposition. Yet while gay political leaders occasionally seem to publicly recognize "our straight allies," many people accept the species view of sexuality, evinced in the wonderment of many respondents and scholars that straight women associate with gay men.

In stating that female friends of gay men may be important constituents and supporters of an agenda of sexual liberation, I do not mean to imply that gay men, lesbians, bisexuals, and transgendered people should turn over leadership of their movement organizations. Indeed, it is these people outside the dominant structure that may often be best able to see its internal inconsistencies and propose progressive changes. Yet if movement organizers wish to effect lasting and important changes, supporters of an ideological movement should be mobilized not on the basis of an identity that is originally defined by the dominant discourse, but on the basis of their shared stake in liberation.

Conclusion

The term *fag hag* is located at the nexus of discourses of gender and sexuality within gay male culture. As such it also resides at a point where hierarchies of difference in gender and sexual identity may be used to define the boundaries of "gay community." The term also relates to other tensions within gay culture: those between rejecting heterosexist domination and rejecting women; between a stable gay community and individuals' sexual freedom; and between the benefits of being presumed straight and those of being seen as part of a gay community. As these tensions are resolved, they determine who is perceived as an outsider to gay culture and how such an outsider will be received.

Furthermore, the term's inclusive, inverted usage suggests that communities of gay men may be much more open to nongay non-men than the rhetoric of gay community would imply. That this rhetoric is used for political mobilization suggests that some mobilization potential may be sacrificed by the strategy of identity politics. The rhetoric of community used to mobilize gay men, for instance, does not necessarily mirror the salient relationships people experience in their own communities, as the comments of these respondents show. Indeed, any political movement for sexual liberation cannot persist for long if it excludes people based on a minoritizing and divisive view of identity, even when their experiences lead them to share antihomophobic goals and those of sexual liberation for which that movement strives.

Notes

1. To preserve confidentiality, all names used are pseudonyms.

2. Three things must be mentioned at the outset: First, for my purposes here, it seems less awkward to follow the current trend and refer to "heterosexual" people as "straight." I will do this throughout the paper, intending no value judgment to accompany the term as some people do when they use it. For my purposes, straight is simply a nonscientific term generally accepted to mean heterosexual without the connotations of an essentializing science.

Second, by using the somewhat awkward phrase, "participants in gay male culture," I wish to make clear that while "gay men" have sets of shared pastimes and beliefs, etc., one need not be gay or male to contribute to and draw from this culture. Furthermore, there are those whom one could call gay who do not share in the cultures to which I am referring. Of course, there

is not *one*, unified gay male culture, but I hope the reader will bear with me and accept that phrase as shorthand for the culture created by men with shared histories of homosexuality in the U.S. who share, among many other things, the term *fag hag*.

Third, synonyms for *fag hag* exist in gay cultures. These include the likes of *fruit fly* and *faggotina*. *Fag hag* is the most common of these terms, however.

3. This article is about the specific case of gay male culture, thus, I exclude from my analysis lesbians, bisexuals and people and groups of many other identities. To examine, for instance, the relations among gay/bisexual men and lesbians, bisexual women, drag queens, and transgendered individuals would undoubtedly complicate, in interesting and valuable ways, the views of gender and sexual identity I present here. Unfortunately, such relations are beyond the scope of this study.

Since the sample does not exclude bisexual male participants in gay male culture, I will clarify one point. Men who identify as bisexual may or may not identify with gay culture. Bisexuality has an extremely complex relationship to gay and lesbian cultures, which should not be overlooked. However, the term *fag hag* emerged in a culture of male homoeroticism, which I give the shorthand abbreviation of "gay (or gay male) culture." Thus, the culture is gay even if not all of its participants are. The relationships between women and bisexual men would add an extra degree of complexity to this analysis and would also be quite interesting to examine more closely.

4. I agree with Foucault's (1980) notion that sexuality consists of discourses that serve as vehicles for power to infiltrate the microlevel, yet towards the end of this article I make clear my agreement with those who build upon Foucault's work (such as Butler 1990, 1993; Patton 1993; Rubin [1984] 1993), suggesting ways in which discourses may be overcome by disrupting the dominant dichotomous notions of gender and sexual identity.

5. In this sense, the term *fag hag* is similar to the practice of drag in Butler's (1993) analysis.

6. As I assert later in this article, even some straight people, such as fag hags, may be seen among gay culture's "insiders."

7. A gay identity is problematic in that an actor must constantly attempt to communicate to others how he or she situates himself or herself. In this way it is similar to identity in the sense used by Stone in his 1962 "Appearance and the Self." Likewise, Patton (1993) shows that a gay identity expresses not so much about an individual's ontology as about her or his personal alliance with a movement.

Suttles (1984) also discusses identity, in his case as something people who live in the same cities use to look for common culture to create a unique and shared sense of "who we are." As all gay men in the U.S. are not united by local ties, however, there is much more room for variation in what people think it means to have a gay identity.

8. Two notable exceptions to this claim are: (1) institutional drag settings such as the stage and big city drag balls, where gay and straight people would mix to view the spectacles drag queens produced, and (2) the gay men and lesbians who embodied visible stereotypes such as that of the "fairy" and the "butch" lesbian. Indeed, while a good deal of work is being done currently suggesting that gay culture pre-Stonewall was not entirely covert, no one contends that most people who engaged in homosexual acts or even lifestyles were as visible or visible in as large numbers as they are today (Bérubé 1990; Chauncey 1994; Kennedy & Davis 1993).

9. Of course, these two stances do not necessarily oppose each other. However, as (1) male homosexuality is not in itself sexist and as (2) sexism and heterosexism are closely linked in that both enforce a system where men dominate women (at both the macrolevel and at the level of individual relations), a conflict may at times arise between resisting heterosexism and resisting sexism. The conflicts and overlap between antihomophobic and antimisogynist agendas have been discussed at length in activist and academic literature. See, for example, King's (1990) "Producing Sex, Theory and Culture" and John D'Emilio's 1983 ground breaker, *Sexual Politics, Sexual Communities: The Making of a Homosexual Minority in the United States, 1940-1970*.

10. There is a good deal of literature about gay identity politics since Stonewall, most notably D'Emilio (1983).

11. Stone (1962) makes the case that social interactions all take place in light of participants' outward appearance, and that unless another appears to be similar to one, one will not be able to identify with, or empathize with the other.

12. My findings also lend support to more recent social psychological work. For instance, Ridgeway (1982) suggests that individuals who differ in salient characteristics from others in a group will succeed in the group if they appear to be group- rather than self-motivated. That fag hags are not seen as threatening in groups where they affirm the value of being gay supports her claim.

13. Some of these women, especially cited among the younger, college-aged respondents, have begun to identify themselves as fag hags, not in any self-depricating way, but either in a way they see as "neutral" or as an empowering act of inversion. Thus, one intermediate contact, leader of his college lesbian, gay, and bisexual organization was once approached by a first-year student, a woman, at the first meeting of the year and was asked, "Can straight people be in your group? I'm a fag hag." (The answer was affirmative.) One respondent, who, unbeknownst to the interviewer had a guest at his apartment during his phone interview said, "Some of them think it's an insult, but some don't mind. For instance, the one in my apartment right now doesn't mind it. In fact, she takes it 'as a compliment, thank you.'" Background laughter made it clear that these two were sharing a lighthearted joke. An investigation of women's use of the term fag hag would make an intriguing counterpart to the present study.

14. To speculate, it seems that the inversion of the term actually contributes to a change in its meaning. For instance, one young respondent does not seem aware that the term has ever had a negative meaning. For Henry, quoted at the beginning of this paper, fag hag refers to his good friends who happen to be straight women. This respondent is twenty years old and has identified with gay culture at a time and place when women and gay men do not have much to divide them. His unawareness of the term's insulting history suggests that as the value assigned to these *relationships* changes, and as more people learn the term by hearing it used in positive ways, the meaning of the term is actually evolving.

15. "Oh, you're such a *fag hag*!" might be used in a lighthearted way, similar to, "Oh, you're such a nut!"

16. Scott's (1992) point that experience is also shaped by discourse is illustrated strikingly in the cases where people believe they could have nothing in common with those of a different sexual identity and therefore shun them, as often happens.

17. This issue is expanded upon by numerous theorists such as Rubin ([1984] 1993), Patton (1993), Seidman (1993), Butler (1990, 1993) and Sedgwick (1990, 1993), who all build upon Foucault's ideas, making the crucial point that discourses legitimate discrimination and violence. Furthermore, Patton, Butler, and others move beyond Foucault by offering a vision of overcoming this power, subverting discourse by challenging dominant categorizations.

18. I would add, following Patton, that no matter how liberating some individuals may find coming out of the closet, as long as there are stable, hegemonically defined categories of sexuality creating identifiable groups of people such as "homosexuals," people's lives will be increasingly policed by these sexual discourses, as I discuss in earlier sections. Patton makes clear that it is important not to confuse the identity rhetorics people use to interpret their place in the world with any statement of their essential being.

19. A similar debate over identity and community has occurred in the literature on Latino/as as a political constituency in the U.S. Some people are quick to point out that there are great differences among various nationalities of Latinos, and argue that the category is therefore a useless contrivance. Others point out that (1) various Latino nationalities do share political views relative to other Americans, and (2) the concept of Latino creates a greater constituency from which to draw political and economic support (Dominguez 1994). A problem for both movements is to find ways to bridge differences within a diverse constituency of people without alienating people the movements purport to represent.

Why Racial Employment Inequality Is Greater in Northern Labor Markets: Regional Differences in White-Black Employment Differentials*

SAMUEL COHN, *Texas A&M University*
MARK FOSSETT, *Texas A&M University*

Abstract

This article investigates employment inequality between 25-59-year-old white and black men in U.S. metropolitan areas in 1980. Greater inequality in employment is observed in the Northeast and Midwest than in the South and West. Regression analysis shows that area variation in employment inequality is closely associated with variation in unionization strength, presence of large firms, and labor demand and that it is moderately associated with variation in race differences in age structure and education and the presence of traditionally black occupations. Regional patterns indicate that the substantially lower employment inequality in the South and West can be attributed to the more robust economies, smaller average firm size, and lower levels of unionization in the metropolitan areas in these regions. These regional differences are large and serve to offset the impact of large racial gaps in educational attainment in the South that often contribute to inequality in employment.

A pressing question in the study of racial inequality in the U.S. is why black employment remains much lower than white employment even as many other socioeconomic gaps between whites and blacks have narrowed. Since World War II, racial differences in education and occupational status have declined and income differentials have also decreased albeit by a smaller amount (Farley 1984; Farley & Allen 1987; Jencks 1991). Even residential segregation has diminished to some degree (Farley & Frey 1994; Massey & Denton 1987). In

contrast, the unemployment gap between white and black males has expanded rather than contracted. In 1948 the white-black employment differential was only four percentage points; by 1987, it was 10 points (Cotton 1989; Jencks 1991).

One fact that is occasionally documented but has been little emphasized and thus is not well known is that white-black inequality in employment is greater in the North and Midwest than it is in the South and West. We find in 1980 among metropolitan areas with a population of at least 250,000 and a black population of at least 25,000[1] that the median gap between white and black employment rates for noninstitutional males 25-59 years old is 15.4 percentage points in the North and Midwest but only 10.7 points in the South and West. Alternatively, employment inequality measured by the ratio of the white odds of employment to the black odds of employment has a median of 3.081 for metropolitan areas in the North and Midwest compared to a median of 2.287 for areas in the South and West.[2] Similar findings have been reported previously by Darden (1983), John Farley (1987), and Shulman (1991). Darden's analysis is hampered by a small sample size. The studies by Farley and Shulman are based on larger samples, but the authors themselves took little interest in the finding of regional differences in the white-black employment gap: Farley devoted only three sentences to this topic and Shulman discussed his regional finding in one sentence.

Regional differences in white-black employment differentials deserve greater attention. One reason is that the differences are sizable and strongly suggest that racial differences in employment opportunities are not uniform, a phenomenon that needs to be explained and interpreted. Another reason is that the pattern is counter to conventional expectations. The South, which has a history of greater racial inequality in education, occupation, and income (Fossett, Galle & Kelly 1986) and which consistently ranks lowest among regions in prevalence of attitudes favoring equality of opportunity and racial tolerance (Fossett & Kiecolt 1989) is characterized by relatively low racial inequality in employment. In contrast, the Midwest and North, which traditionally have been seen as affording greater socioeconomic opportunities to blacks, are characterized by the greatest inequality in employment. For most of this century, the Midwest and North attracted black migrants from the South because racial inequality in occupation, education, and income and measured racial prejudice have consistently been lower in these regions.

Only one other important measure of racial differentiation — residential segregation — has been documented to be higher in the North and Midwest than the South (see, e.g., Massey & Denton 1987) and evidence for this regional difference is mixed until recent decades. Massey and Denton present data compiled from a number of studies showing residential segregation to be lower in selected southern cities in 1860 and 1940 (1993:21). On the other hand, segregation measured by block data for large cities showed southern cities to have equal or higher levels of segregation than nonsouthern between 1940 and 1970 (Sørensen, Taeuber & Hollingsworth 1975). For recent decades, findings on regional differences are more consistent. Massey and Denton report lower levels of segregation in the South in 1970 and 1980 (Massey & Denton 1987) and in 1990 (Massey & Denton 1993) for analyses using tract data for metropolitan areas. Farley and Frey (1994), using similar data, also report less segregation in

the South in 1990. It is interesting to note, however, that Massey and Denton (1993) and others (e.g., Roof, van Valey & Spain 1976) have interpreted differences between residential segregation in the South and that elsewhere as anomalies that are due at least in part to the region's special historical conditions and the ecological characteristics of southern metropolitan areas. It is significant that no major statement has argued that lower levels of residential segregation in the South are indicative of greater relative socioeconomic opportunities for blacks in this region.

We address the need for more detailed analysis of regional variation in white-black employment differentials in this article. Using a regression-based decomposition of racial employment differentials in 99 metropolitan areas in 1980, we find that lower racial inequality in employment in Sun Belt metropolitan areas is primarily due to lower levels of unionization, higher rates of economic growth, and smaller firm size in these areas. These factors counteract the greater educational inequality between blacks and whites in the South that usually contributes to racial inequality in employment. We interpret our findings as being consistent with the view that racial employment differences reflect employer discrimination in hiring and that such discrimination is shaped by factors such as loose labor markets that give employers more latitude in hiring decisions and factors such as larger, more bureaucratic organizations and greater unionization, which limit managerial discretion in firing and promotion policies and tend to shift employer discrimination toward the hiring process.

Descriptive Analysis

We focus here on the gap between white and black employment rates, not the absolute rates of black employment. Low levels of black employment could well be the function of a depressed economy, which hurts blacks and whites alike. It is more important for the study of racial inequality to assess, given the jobs locally available, whether all groups have equal access to employment opportunities. We measure employment for each group relative to each group's civilian, noninstitutional population; we specifically avoid using traditional unemployment rates. The latter registers the ratio of "officially" unemployed workers to total civilian labor force. This is unsatisfactory for our purposes because adverse labor market conditions may push many otherwise willing workers out of the "official" labor force entirely. Jeremiah Cotton (1989) has shown that excluding these "nonparticipants" from official unemployment rates substantially underestimates the severity of racial gaps in employment. Thus, we focus instead on the ratio of employed civilian workers to the noninstitutional, civilian population.[3] We further restrict our focus to men in the prime working ages of 25-59 to try to minimize the potential distorting influence of area variation in school enrollment (especially college), female labor force participation, and retirement populations.

The racial inequality in employment can be measured in a number of ways. For our purposes, the most attractive measure is the relative odds of white and black employment; that is, the ratio of the white odds of employment to the black odds of employment.[4] This measure has the advantage of being simple to

interpret. For example, a score of 2.5 indicates that the odds of employment for whites are two and one half times as high as those for blacks. In addition, the logarithm of this ratio — the relative log-odds of employment — is appropriate for regression analysis.[5] Finally, the relative odds of employment is not sensitive to variation in aggregate employment. In contrast, the white-black difference in employment rates increases when aggregate employment falls, even when the relative odds of employment are constant.[6]

Table 1 presents relative odds of white and black employment for U.S. metropolitan areas in 1980. Unlogged odds are presented, since it is the more familiar descriptive measure. The relative log-odds used in our regression analyses appears as Appendix A. Of course, the rank ordering remains identical after the log transformation.

The estimates presented in Table 1 are computed from data reported in the 1980 U.S. Census of Population based on area-specific samples of approximately 1 in 6 persons from each metropolitan area.[7] The sample of metropolitan areas

for which the measure of employment inequality is computed includes 99 metropolitan areas with total populations of at least 250,000 and black populations of at least 25,000.[8] Given the limitations of the published tabulations, our results do not generalize to smaller metropolitan areas or to large metropolitan areas with small black populations. Data for blacks are based on the census race category "Black or Negro." Data for whites are based on the non-Hispanic white population.[9]

It is not surprising that Table 1 shows that employment inequality favors whites in all metropolitan areas in our sample. Relative odds ratios above 1.0 indicate that white odds of employment are greater than black odds of employment; the higher the value, the greater the inequality in employment. The median value for the full sample is 2.599 and indicates that in the typical city the white odds of employment are about 2.6 times greater than the black odds of employment. The lowest relative odds ratio is observed for Daytona Beach, Florida (1.254); the highest is observed for Grand Rapids, Michigan (4.271).

The data reveal considerable variation in employment inequality across areas and regions. The variation across areas is indicated by the interdecile range of 1.777 to 3.620 for the full sample.[10] Important variation in employment inequality by region is revealed by the medians for the regional subsamples. They show that racial inequality in employment is higher in the Northeast and Midwest, which have sample medians of 2.852 and 3.105, respectively, and lower in the South and West which have sample medians of 2.318 and 2.105, respectively. Other comparisons corroborate the basic pattern suggested by the regional medians. Only 12% (6) of northeastern and midwestern cities are below the median for the full sample of metropolitan areas; in contrast, fully 72% (43) of Sun Belt cities fit this description. Similarly, 18 of the 20 highest relative odds ratios (the uppermost quintile) are located in the Northeast and Midwest while 17 of the 20 lowest relative odds ratios (the lowest quintile) are located in the South and West. It is interesting that 7 of the 10 lowest relative odds ratios are located in Florida. To reiterate the most important finding, the regional differences are sharp and substantively important; white advantage in the odds of employment is consistently higher in the Northeast and Midwest.

The Case for a Decomposition Analysis

The distribution of inequality across regions documented in Table 1 is counterintuitive in light of traditional findings of marked regional differences in racial prejudice and attitudes toward equality of opportunity (e.g., Giles 1977; Pettigrew 1959; Schuman, Bobo & Steeh 1985; Sheatsley 1965; Taylor, Sheatsley & Greeley 1978) and marked regional variation in racial inequality in education and occupation (Wilcox & Roof 1978). These lead to an expectation of greater employment inequality in the South. To explain these large regional differences in racial employment inequality we adopt the following strategy. First, we identify characteristics of metropolitan labor markets that theory suggests are likely to influence racial employment inequality. We then perform a regression analysis that which estimates the effects of these variables. Then we investigate

the extent to which regional differences in the structural characteristics of the metropolitan labor markets account for variation in average levels of racial employment inequality across regions.

Our interest is thus focused on three questions. One is whether the metropolitan characteristics we identify can be confirmed as important predictors of employment inequality. Another is whether regional differences in distributions on these variables can account for regional differences in employment inequality. The final question concerns how patterns of regional distribution on the metropolitan characteristics contribute to generating regional differences in employment inequality.

In this section we selectively review potential determinants of racial employment inequality. We draw on a variety of intellectual perspectives, each of which we believe has validity in at least some analytical contexts. These perspectives suggest several variables that are likely to generate interarea variation in racial employment inequality. We do not presume that the variables developed here include all factors likely to influence racial inequality. We argue only that it includes many variables that are likely to be both important determinants of racial employment inequality and germane to explaining regional differences in racial employment inequality.[11]

HUMAN CAPITAL THEORY

Human capital theory suggests that racial differences in human capital investment will generate racial differences in employment. Some forms of human capital — namely, on-the-job experience — are acquired through employment and are thus are inextricably bound up with differential access to employment. To invoke these differences in a cross-sectional analysis is to advance an explanation that borders on tautology; blacks are more likely to be unemployed because they have less of the training that is acquired through employment. Human capital differences reflected in differences in formal education originate outside the employment process and are less troublesome methodologically.[12] In his cross-sectional analysis, John Farley (1987) found that larger racial education differences in an area were associated with larger unemployment gaps. Shulman (1987) also found that area variation in mean education was positively but differentially related to employment rates for both blacks and whites, implying that greater race differences in education will generate greater employment inequality.

The reasoning outlined above emphasizes the aggregate consequences of the individual-level effect of education on employment. An altogether different line of reasoning draws on the theory of statistical discrimination (Phelps 1972; Thurow 1975) to argue that education differences may have important consequences for racial employment inequality. This perspective does not emphasize the role of education in individual attainment per se. Rather it argues that large group differences in education may encourage employers to engage in statistical discrimination. That is, it increases the likelihood that employers will more readily rely on race as an inexpensive and readily observed surrogate for quantity or quality of education (Phelps 1972). This implies that race differences in returns to education will be diminished in cities where race differences in

education are large. Thus, the employment prospects of even better-educated blacks are reduced when lower relative educational attainments for blacks as a group induce employers to statistically discriminate against blacks.

These arguments lead to the prediction that racial education differences will have a positive effect on racial employment inequality. Confirmation of this prediction in the present context will not permit a distinction between the two theoretical motivations for expecting the relationship. However, regardless of the theoretical interpretation assigned to the effect, it is likely to have important consequences for regional variation in employment inequality since racial education differences are considerably more pronounced in the South than in other regions.

LABOR DEMAND AND QUEUING THEORY

Thurow (1975), Hodge (1973), Lieberson (1980), and Reskin and Roos (1990) have argued that employment outcomes are determined by a queuing process. In this process, employers first rank potential workers by relative attractiveness (however defined) and then hire the top-ranked job candidates and then continue hiring from successively lower ranks in the candidate queue until all available openings are filled. In this model, employers hire more attractive workers before less attractive workers and, as labor demand increases, employers must move farther down the queue and hire workers who would be excluded under conditions of slack labor demand.

Thurow's discussion of queues emphasizes the ranking of prospective employees on human capital characteristics and employer perceptions of trainability. However, any criteria including ethnic background can be used for the purpose of ranking potential workers in an employment queue (Hodge 1973; Reskin & Roos 1990). Thus, for example, in a discriminatory queue, employers may rank white applicants ahead of black applicants. Such rankings may well reflect overt prejudice as when employers choose white workers over similarly or even more highly qualified black workers. Alternatively, ethnic ranking may be rationalized in terms of presumed correlations between ethnicity and work habits, quantity and quality of human capital stocks, or other productivity-related characteristics (e.g., ethnic stereotypes and statistical discrimination). Statistical discrimination may be further encouraged by the fact that race and ethnicity are readily observable characteristics that are relatively easy to measure compared to many non-ethnic characteristics of interest to employers (e.g., quality of education, drug use, criminal records, etc.).[13] Recent work by Kirshenman and Neckerman (1991) documents the pervasiveness of prejudice-based and especially statistical discrimination by employers and strongly suggests that race continues to be an important factor in the ranking of potential employees.

When workers in labor queues are ranked at least in part on ethnic characteristics, racial employment inequality will be affected by overall labor demand. This of course is the model implicitly invoked by the familiar last-hired/first-fired scenario. Queuing theory predicts that the higher the rate of overall employment, the lower the employment gap between whites and blacks. Evidence for this relationship can be found in previous comparative research.

For example, Shulman (1987) found that the white-black employment ratio was negatively associated with total employment and Williams (1987) reported that blacks were disproportionately likely to be pushed out of the labor force altogether when global unemployment rates were high.

Regional differences in economic growth have been pronounced in recent decades with the South and West experiencing consistently stronger labor demand. In view of this, labor demand is likely to be a potent explanation of regional differentials in racial employment inequality.

ESTABLISHMENT SIZE

Dual labor market theory argues that large monopoly sector firms are more likely to discriminate than smaller firms in the competitive sector. The superior market position of large primary sector firms buffers them from having to minimize labor costs, allowing them to tolerate higher levels of discrimination than would occur elsewhere in the economy (Averitt 1968; Cohn 1985; Kalleberg, Wallace & Althauser 1981). This leads to the prediction that firm size (an available indicator of the presence of primary sector firms) will have a positive effect on racial employment inequality.

A potential problem with this application of dual sector theory is that it fails to consider predictions from an affirmative action model. This view suggest that large firms (and especially those with government contracts) may be subject to greater enforcement of equal opportunity and affirmative action guidelines. For example, Title VII enforcement is limited to firms with more than 15 employees and Executive Order 11246 rules for federal contractors applies only to firms with 50 or more employees. There is a substantial body of evidence that suggests that affirmative action programs have increased opportunities for blacks in at least some respects, although scholarly debate on this topic continues (Burman 1973; Freeman 1973; Heckman & Payner 1989; Heckman & Wolpin 1976; Vroman 1975).

One possibility, however, is that equal employment opportunity guidelines may have an effect on employment that is different from that of other factors, and more perverse. Namely, the applicability of equal employment opportunity regulations may foster more equal outcomes on wages, job assignments, promotions, layoffs, dismissals, etc. for minority workers who are employed in large firms. However, it may also lead employers and firms to be more selective in their hiring given that they may have less flexibility in their dealings with workers once they are hired. If such selectivity in hiring is correlated with firm size and if race is a factor that is salient in selective hiring, then firm size could have a positive effect on employment inequality.

We have noted arguments for two opposite and potentially offsetting effects of establishment size. However, on the whole, we expect dual labor market effects to dominate affirmative action effects. One basis for this prediction is that establishment size is highly correlated with superior market position but only weakly correlated with enforcement of affirmative action legislation. The relationship between establishment size, market share, and superior market outcomes have been well established in the empirical literature (Hodson 1978; Wallace & Kalleberg 1981). In contrast, the enforcement of affirmative action

and equal employment opportunity regulations has been sporadic and only weakly associated with any obvious industrial attributes (Heckman & Payner 1989; Jaynes & Williams 1989; Vroman 1975). In addition, equal employment regulations may promote less equality than we anticipate because of differences between their direct effects on employment inequality and their indirect effects from employer reactions to being regulated. Therefore we expect the dual sector effects to predominate.

A pattern of regional differences in firm size is not widely noted in the sociological literature. However, the existence of such regional differences combined with the predicted positive effect of firm size on employment inequality obviously could contribute to regional variation in racial employment inequality.

UNIONISM

The presence of organized labor in a metropolitan labor market may also increase employment inequality between whites and blacks. Gary Becker (1957) argued that employee prejudice may be as important as employer racism in determining racial inequality. Welch (1967) and Arrow (1972) have also advanced models in which inequality flows from white workers' resistance to working with minority workers (either due to prejudice or self-interest). Many employers claim to be reluctant to hire minorities because of perceived opposition from their preexisting and predominantly majority labor forces (Braddock & McPartland 1987). Such arguments have to be viewed with some skepticism (Reich 1981). Although organized labor has a record of racism, its racism has been concentrated in a small number of craft unions (particularly New York construction unions) that have received a disproportionate share of scholarly attention (e.g., see Foner 1974; Hill 1984; Jacobson 1968).

Ashenfelter (1971) argues convincingly that the patterns in such studies are atypical. He maintains that union discrimination will occur only when two conditions are met simultaneously. First, trade unions must have significant control over the hiring process. If employers control entry into jobs, then exclusionary policies by unions will be ineffective and irrelevant to racial inequality in employment. Second, the union must be capable of generating credible strike threats without organizing 100% of the potential work force. If the presence of unorganized workers can vitiate labor's bargaining strength, then unions have little choice but to attempt to organize all workers regardless of ethnic origin. Ashenfelter argues that these two conditions only apply to craft construction unions; he presents data that suggest that racial differences in both percentage unionized and wage rates are found primarily in construction trades (Ashenfelter 1971).

American unions, and in particular CIO unions, have been forces for reducing rather than raising racial inequality within the employed labor force. The CIO, and later the AFL-CIO, was an early and forceful supporter of the civil-rights movement (Marshall 1965). Many CIO unions were known for their militant defense of equal rights for blacks in the workplace. Among these are the Packinghouse Workers, the Electrical Workers, the United Mine Workers, and the San Francisco longshoremen (Fogel 1970; Foner 1974; Kimeldorf 1988;

Northrup 1944). There is at least some evidence that American unions overall have reduced income inequality between whites and blacks. Richard Child Hill (1974) has shown for a sample of U.S. metropolitan areas in 1960 that unionization was correlated with lower racial inequality in family income. Freeman and Medoff (1984) report findings that union membership raises blacks' wages more than whites', although the difference is statistically significant only in some periods.

These theoretical and empirical findings lead us to accept the general conclusion that union efforts are likely to reduce racial inequality among workers already employed. However, we argue that employer adaptations to organized labor may well increase racial inequality in access to employment. Collective bargaining agreements constrain the exercise of managerial discretion in firing and promotion decisions. Union contracts generally specify bureaucratic systems of job assignment and wage scales. Likewise they commonly specify grievance procedures and provide contractual protection against arbitrary dismissal. Enforcement of these negotiated rules concerning the internal labor market of the firm restrict management's capacity to discharge workers at will (Freeman & Medoff 1984; Jacoby 1985; Slichter 1960). This is likely to reduce discrimination against employed blacks by protecting them against arbitrary actions by supervisors.

At the same time, the resulting reduction in managerial discretion in firing and promotion may raise barriers to the employment of blacks. Discriminatory employers are likely to be especially reluctant to hire black workers when they know that once hired these workers will derive protection from structured labor-management relations. Thus, Jacoby (1985) argues that employers respond to externally induced limitations of their right to fire with more intensive screening of potential workers. This may lead some employers to give greater emphasis to statistical discrimination by race in hiring. More important, it may lead employers to rely to a greater degree on formal qualifications and credentials such as licenses, certificates, and educational degrees and informal factors such as employer and employee references. Screening potential employees in this way is likely to have a disproportionate negative effect on black employment.

If greater unionization does have the net effect of shifting discrimination toward the point of hire and thereby increases racial inequality in employment, we would expect unionization to have important implications for regional variation in racial employment inequality. The Northeast and Midwest have considerably greater unionization than the South (though not necessarily the West), and thus our prediction would suggest that lower employment inequality in the South may be traceable in part to its lower percentage of unionization.

OCCUPATIONAL COMPOSITION

Regional differentials in racial employment inequality may be a function of differences in occupational composition. Traditionally, blacks have been underrepresented in professional, managerial, sales, clerical, and skilled blue-collar occupations. In part this may reflect a degree of uniformity in norms regarding the "appropriateness" of minority employment in certain occupations.

Alternatively, it might reflect consumer discrimination (e.g., professional specializations serving predominantly majority clientele). This would mean that, even in the absence of differences across areas in the propensity to discriminate, variation in racial employment inequality might follow variation in the supply of "appropriate" employment opportunities. Overall, these differences in occupational composition would trace to differences in industrial composition and the technical requirements of each industry. However, the proximate effect is likely to be felt through occupational composition. Thus, we would expect to see an inverse relation between racial inequality in employment and the prevalence of occupations "favorable" to black employment. If such occupations are regionally concentrated, then this would contribute to an explanation of regional differences in employment inequality.

AGE STRUCTURE

Another possibility is that the racial employment differences reflect differences in age structure. Age groups vary considerably in their rates of participation in the labor force. Workers in the "prime" years (30-49) have the highest labor force participation rates. Younger adults and older adults have weaker attachment to the labor force. Cities do differ significantly in their age structures and white and black age structure may vary independently. We noted earlier that seven of the ten cities with the lowest relative odds are located in Florida. One possible explanation for this is that the age composition of whites in Florida cities is skewed toward older ages with lower labor force attachment. With this in mind, we predict that employment inequality will tend to be greater in areas where whites have age structures that favor greater labor force participation and employment. If racial differences in age structure vary by region, this factor may then contribute to an explanation of regional differentials in racial employment inequality.

SPATIAL MISMATCH

Race differences in access to jobs resulting from residential segregation has been suggested as a possible explanation of white-black employment inequality (Kain 1968; Kasarda 1990). To the extent that "spatial mismatch" generates employment inequality and varies by region, it could contribute to regional variation in racial employment inequality. This possibility is suggested by the fact that studies advancing the spatial mismatch hypothesis have tended to focus on large urban areas in the Northeast and Midwest.

Unfortunately, it is impossible at this time to subject the spatial mismatch hypothesis to a direct test in a comparative analysis because satisfactory measures of mismatch between spatial distributions of residence and jobs are not available for metropolitan areas. Residential segregation cannot be used as a proxy because it reflects residential distributions only and does not register the distribution of jobs (Galster 1987). Measures of mismatch based on central city-suburb distinctions are simply too crude. They reduce urban space to a dichotomy and ignore job and residential distributions within the suburban ring and the central city. This is a potentially significant problem in cities such as

Chicago where it matters very much whether a job is located on the north or south side of the city (Ihlandfeldt & Sjöquist 1989; Kain 1974). Perhaps an even more important problem is the fact that central city definitions are more expansive for newer cities in the South and West (due to the greater opportunities these cities have had to grow by annexation) and thus cross-region comparisons of mismatch measures based on central-city suburb distributions are highly questionable. In view of these problems, investigation of mismatch effects must be left to future research.[14]

RACIAL INTOLERANCE

Variation in racial inequality is sometimes explained with a simple culturalist model of discrimination (Heer 1959; Myrdal 1944; Schuman, Bobo & Steeh 1985). Presumably, white advantages in employment would be greater in areas where attitudes of white race prejudice and intolerance are most pronounced. However, this would not seem to be a likely candidate for explaining the lower racial employment inequality in the Sun Belt since the literature on white racial attitudes has consistently found Southerners to be more likely to acknowledge racial intolerance and to express less enthusiasm for equal opportunity initiatives (Fossett and Kiecolt 1989; Giles 1977; Taylor, Sheatsley & Greeley 1978). It might simply be that racial attitudes affect employment inequality according to conventional expectations and that, all else equal, regional culture fosters greater employment inequality in the South. This might then be counteracted by the inequality-reducing effects of other regional differences. Unfortunately, the lack of area-specific measures of white racial attitudes for a large sample of metropolitan areas prevents us from including direct measures of racial attitudes in the main multivariate analysis reported below. We do however provide a supplementary analysis that attempts to address this issue.

Data and Measures

The measurement of employment inequality and the nature of the metropolitan sample were described earlier. We now briefly describe the operationalization of independent variables included in our regression analysis of employment inequality. A measure of racial education differences was developed from metropolitan statistical area (MSA)-specific census tabulations. For each MSA, educational attainment was coded on a seven-point scale as follows: 0-4 years = 0, 5-7 years = 1, 8 years = 2, 9-11 years = 3, 12 years = 4, 13-15 years = 5, and 16+ years = 6. (This coding follows census educational categories, which emphasize the importance of key credentialing years).[15] Following Fossett and South (1983), we measured inequality by calculating the difference in mean education between whites and blacks and then expressing it as a percentage of the mean education of the group with the higher level of education (in our sample, this was whites in every city).[16]

Labor demand was measured by population change in percentage between 1970 and 1980.[17] Population change is a close proxy for labor force growth, an indicator of long-term labor demand. The cross-sectional correlation between labor force and population exceeds 0.99. This strong correlation justifies using

population growth as a surrogate measure for labor force growth — a considerable practical advantage since it is easier to obtain measurement for population over time based on constant-area MSA definitions.

Prevalence of large firms was measured by the percentage of firms employing 20 or more workers. This is one of the few firm-level indicators that is reported for all industries in the metropolitan areas as opposed to only firms engaged in manufacturing. County-level data were taken from County Business Patterns for 1980 and were aggregated to the metropolitan level. Results for this variable are similar when other cut points were used (e.g., the percentage of firms employing 50 or more workers) and when we used measures of median firm size developed from the firm size distributions.

Union membership data for 1980 come from the U.S. Statistical Abstract's compilation of data from the U.S. Bureau of Labor Statistics. It is measured at the state level and assigned to metropolitan areas (MSAs spanning state borders are assigned an average score). While this is by no means an ideal measurement strategy, alternative MSA-level measures of unionization (e.g., CPS-based estimates from Kokkelenberg and Sockell 1985) are also problematic since they are available for only a small number of areas and are based on area-specific samples of individuals, which are often small.[18] The assignment of state-level unionization scores to metropolitan areas obviously introduces measurement error. However, more reliable estimates are not available and the measurement error introduced should be largely random rather than systematic.[19] Thus, it will tend to attenuate the estimated effect of unionization.

The favorability of the occupational composition to black employment was estimated by using census occupation tabulations to calculate the "expected" black representation in the labor force given the metropolitan area's occupational mix. This was obtained by computing the product of the proportion of the metropolitan area labor force in a given occupation and the percentage representation of blacks in that occupation at the national level and summing these products over all occupations.[20]

The potential impact of race differences in age structure on race differentials in employment was estimated by using census data to calculate the expected employment-to-population ratios for each race in each metropolitan area based on age distributions for each group and national race-age-labor force status tabulations.[21] The expected employment-to-population ratio for whites in the metropolitan area was then expressed as a ratio of the similar figure for blacks and then subjected to a log transformation to obtain an expected relative log-odds of employment based on black-white differences in age composition.

Findings

Table 2 reports the OLS regression of the relative log-odds of employment (i.e., the natural logarithm of the ratio of the white odds of employment to the black odds of employment) on the predictors in the model. The model explains most intermetropolitan variance in racial employment inequality (approximately 70% as indicated by the adjusted R^2). More important, the independent variables all exhibit statistically significant effects in the predicted directions. That is to

say, relative white advantage in employment is greater in areas where race differences in age structure favor white employment, education differences between whites and blacks favor whites, population growth is slow, large firms are prevalent, union membership is high, and representation of occupations favorable to black employment is low. In general then, the predictions about area variation in racial employment inequality developed from human capital theory, queuing theory, and dual labor market theory and from expectations about the impact of occupation mix and race differences in age structure are supported. Two variables, unionization and firm size, appear to be especially important — at least as their respective standardized regression coefficients (betas) of 0.511 and 0.463 seem to indicate. Population growth also stands out as being an important predictor with a standardized regression coefficient of -0.316.

Explaining Regional Differences

We now turn to consider the central question of this article. That is, "What explains the pattern of regional variation in racial employment inequality?" Table 3 presents data on regional differences in the characteristics of metropolitan areas that bear directly on this question.

Considerable insight into regional differences in employment inequality can be gained by examining the data in Table 3 in conjunction with the regression results presented in Table 2. A large regional difference in the means for a given metropolitan area characteristic combined with a sizable coefficient for that characteristic in the regression would suggest a potentially important contribution to regional differences in racial employment inequality. With this in mind, three regional differences in metropolitan area characteristics — namely, population growth, unionization, and firm size — are most important in generating the regional differences in employment inequality observed in Table 1.

Population growth had a negative effect on employment inequality in the regression analysis and metropolitan economies in the Sun Belt were growing rapidly. Average population increases over the decade were approximately 23% in the South and 29% in the West. In contrast, metropolitan economies in the Frost Belt were stagnant, as indicated by average population increases near zero in the Northeast and the Midwest. These patterns contributed to higher employment inequality in the Northeast and Midwest and lower inequality in the South and West. Regional differences in unionization had similar consequences. Unionization had a positive effect on employment inequality, and unionization was decidedly lower in the South and higher in the Northeast and Midwest; the West tracked in between but closer to the Frost Belt. The most striking comparison, of course, is the South versus the Frost Belt, for union membership in the South was lower by about half (15% compared to 30%). Regional differences in firm size were less dramatic. However, the positive effect of firm size on employment inequality contributed to higher inequality in the Midwest, and lower inequality in the West, Northeast, and South.

[a] U.S. SMSAs 1980. All coefficients are significant at the .05 level in a two-tailed test. The constant is not presented but is used in predicted values in subsequent tables.

The other regional differences in metropolitan area characteristics either had no major consequences for employment inequality or had consequences that ran counter to the general pattern of regional differences in employment inequality. Regional differences in both age structure and occupational mix were modest in size and generally did not have important or systematic impacts on regional differences in inequality. Regional variation in racial education differences are considerable, but the consequences for inequality did not contribute to regional differences in inequality in a simple way. The average metropolitan area in the South exhibited a white advantage in education over blacks of almost 24 percentage points compared to only 15 or 16 in the Northeast and Midwest. The West was lower still, with an average below 11%. Thus, racial education differences contributed to higher employment inequality in the South, lower inequality in the Northeast and Midwest, and considerably lower inequality in the West.

Table 4 presents a more systematic quantification of the contribution of regional differences in the characteristics of metropolitan areas to regional variation in racial employment inequality. The first row of the table presents the regional means of the dependent variable (i.e., the relative log-odds of employment) as deviations from the mean for the national sample. This shows that metropolitan areas in the Northeast and especially the Midwest are well above the national average on racial inequality in employment. By comparison, metropolitan areas in the South and West are well below the national average.

The next six rows of the table (under "Percent of Difference Due to") list the contribution of each region's departure from the national average for each characteristic to its departure from the national average for employment

TABLE 3: Means of Predictor Variables by Region[a]

	Northeast	Midwest	South	West	Total

$R^2 = .71$
Adjusted $R^2 = .71$

inequality. They were calculated in the following manner. First, the regional mean (in deviation form) of each independent variable was multiplied by the unstandardized regression coefficient for that predictor reported in Table 2. This represents the region's expected deviation from the national average on inequality associated with the region's deviation from the national average on the independent variable in question. This figure was then divided by the observed regional mean of the dependent variable (again in deviation form).[22]

The result is the contribution of the regional differences in metropolitan area characteristics to regional differences in employment inequality expressed as a percentage of the observed regional deviation on employment inequality. The conversion of the contribution of each regional deviation to a percentage interpretation greatly facilitates comparisons of the importance of variables. For example, the greater population growth in southern metropolitan areas contributes 32.88% of the deviation of metropolitan areas in the South of -0.115 from the national average on the relative log-odds of employment. This is not inconsiderable, but it is dwarfed by the impact of the deviation of Southern metropolitan areas on unionization, which generates a deviation on inequality that represents fully 103.29% of the observed southern deviation from the national average on inequality.

The bottom row of the table provides the sum of the separate contributions. If regional differences were entirely captured by these independent variables, the separate contributions of each variable would sum to exactly 100% of the observed regional deviation. Sums below 100% indicate that the model underpredicts the regional deviation on employment inequality. Sums above 100% indicate that the model overpredicts the regional deviation on employment inequality.

Inspection of Table 4 reveals that most of the Northeast's high inequality can be attributed to its high unionization and low population growth. At

TABLE 4: Regression-based Decomposition of Regional Differences in White-Black Employment Gap

Unionization	96.30	49.16	103.29	-38.54
Sum of separate contributions	90.82	91.00	72.63	139.44
N	18	21	45	15

contributions of 96.3% and 62.34%, respectively, these two components dwarf the other metropolitan area characteristics considered in the analysis. These contributions to higher average inequality are offset somewhat by the presence of small firms and a certain equality in educational opportunity.

Higher average inequality in the Midwest stems primarily from above-average unionization and firm size. Below-average population growth makes a lesser contribution to inequality. The only major factor reducing inequality is the region's relative educational equality.

As noted previously, the relatively low employment inequality for metropolitan areas in the South can be traced to its below-average unionization and above-average growth, unionization being the far more important factor. The only other factor of consequence is the much higher educational inequality in the South, which greatly increases employment inequality and more than offsets the ameliorating effects of growth.

The pattern in the West does not resemble that observed for any other region. Very slight racial inequality in education contributes more than 90% to the region's observed deviation on employment inequality. Sizable contributions to lower average inequality can also be traced to high average population growth and small average firm size. Higher unionization and an occupational mix unfavorable to black employment contribute to higher employment inequality, but these contributions are modest in size and hardly counterbalance the large effects of low education differences and high growth in the West.

Overall, the model in Table 2 does a good job of reproducing the regional variations in average employment inequality. The predictions are very close for

the Northeast and Midwest and close for the West and South. In the Northeast and Midwest the predicted regional deviations on inequality sum to about 91% of the observed deviations for these regions. These figures are very close to the ideal of exactly 100%. The model underestimates the extent of Southern employment inequality, and overestimates the amount of Western employment inequality. However, predicting 73% of the Southern differential and 139% of the Western differential can be viewed as acceptable performance. Figure 1 shows these differences graphically. It confirms that, in general, the model is helpful in understanding how regional differences in racial employment inequality are generated.

A formal assessment of our model's ability to explain regional differences in racial employment inequality is presented in Table 5. This table presents five regression analyses. The first is our "core model." The second is a model that includes dummies for region only, omitting the Midwest. The third is a model that adds region dummies to our core model. The fourth and fifth models repeat the analysis of region using a two-category Sun Belt-Frost Belt scheme, omitting the Frost Belt in panel E.

Our analytic model explains most of the effects of region in the four-region analysis and all the effects of region in the Frost Belt-Sun Belt analysis. As seen in panel B, region has large and important effects when considered in isolation. However, the explanatory power of the model increases dramatically and regional effects are sharply attenuated when our substantive predictors are added to the model. In panel C, the adjusted R^2 increases to 0.72 (compared to 0.30 in panel B), the deviations associated with the Northeast and the West are near zero, and the deviation for the South is only slightly greater than half its value in panel B. By comparison, the addition of the regional dummies to the core model leads to only a small increase in ability to explain variation in racial employment inequality (the adjusted R^2 increases from 0.71 to 0.72 between panels A and C).

Figure 1 illustrates this goodness of fit graphically. The observed regional deviations in the white-black relative log-odds of employment are charted against those deviations that would be expected from the model in Table 2. The observed and expected graphs are very similar. Clearly, only a small portion of the variation in racial employment inequality can be uniquely attributed to regional effects not captured by our substantive variables.

An Alternative Specification with Racial Attitudes

One objection that can be raised against the analysis presented in Table 2 is that it does not take account of discrimination based on race prejudice. As we argued above, it is not immediately obvious that inclusion of such a variable is important to accounting for regional variation in racial employment inequality since the literature on racial attitudes shows higher levels of racial tolerance in the Northeast and Midwest where observed employment inequality is high (Fossett & Kiecolt 1989; Giles 1977; Middleton 1976; Taylor, Sheatsley & Greeley 1978; Wilson 1986). Nevertheless, we do not dismiss the possibility that normative climates reflected in racial attitudes may have an independent effect

on hiring decisions that might, if adequately captured, alter the results just reviewed.

We investigated this issue by obtaining average scores on white racial tolerance at the community level generated using data from the 1976 and 1977 General Social Surveys (Davis & Smith 1978).[23] These years were selected because they contained relevant questions on racial attitudes and because community-level information was available (Stinchcombe & Taylor 1980) which permitted identification of 55 metropolitan areas, 45 of which were included in our sample. Note that because data were available only for 45 cities, it was impossible to include these materials in the primary 99-city analysis. Racial tolerance was measured for individuals based on a four-item index similar to those used in previous analyses of racial attitudes (e.g., Fossett & Kiecolt 1989; Taylor, Sheatsley & Greeley 1978; Wilson 1986), but limited to items that

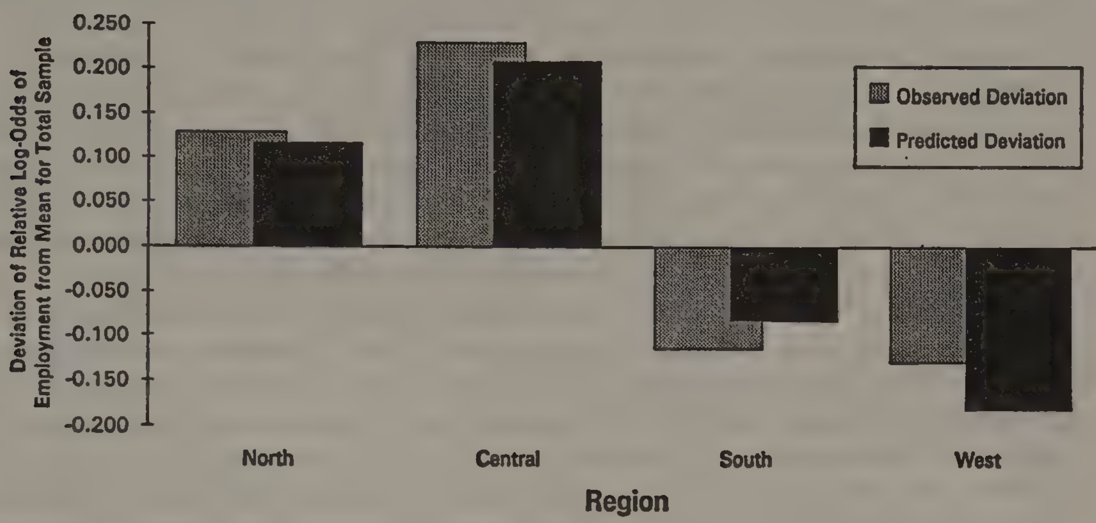
measure adherence to the principle of racial integration (Schuman, Bobo & Steeh 1985). Respondents were asked whether whites have a right to racial residential segregation, whether blacks and whites should go to the same schools or to different schools, whether there should be laws against marriages between blacks and whites, and whether blacks should "push" themselves where they are not wanted. Individual responses to these four items were coded so higher scores indicated greater tolerance or acceptance of integration and were summed to create an index with scores ranging from 4 to 12 with higher values indicating greater support for racial integration.[24]

Area-specific means of the individual index scores were computed for each metropolitan area included in the GSS sample. The average level of white racial tolerance varied meaningfully and significantly across metropolitan areas ranging from a low of 6.07 for Birmingham, Alabama, to a high of 9.66 for San Francisco. Unfortunately, despite combining two years of the GSS, the area-specific samples of individuals were not large (e.g., the median sample size over the 45 metropolitan areas in our sample was 26) and the racial tolerance means were less than wholly reliable (the median standard error of the area-specific racial tolerance means was 0.41). However, this measure of racial tolerance varied across areas in ways that appeared sensible based on a working knowledge of race relations in the U.S. (e.g., lower scores in the South and higher scores in areas with high levels of education and income) Thus, while imperfect, it is useful and represents the best available direct measurement of white racial attitudes in different metropolitan areas known to us.

FIGURE 1: Observed versus Predicted Regional Differences in the White-Black Relative Log-Odds of Employment



We added the racial tolerance means as an independent variable in our data set and reestimated the regression equation presented in Table 2 using the smaller sample of 45 cases for which the racial tolerance means could be computed. The results of this analysis are presented in Table 6. Two important findings warrant discussion. The first is that racial tolerance has no significant impact on employment inequality. The effect of white attitudes is both substantively small and statistically insignificant. The second finding is that most of the effects of the other predictors in the model are unaffected when racial attitudes are included as a control. With the exception of age structure differences, every variable maintains its sign, approximate size, and significance. Age structure becomes insignificant, but this variable had already been found to contribute little to our substantive understanding of regional differences in employment inequality. Variables that were previously identified as having important consequences for interregional variation in racial employment inequality — economic growth, unionization, firm size, and educational differentials — continue to have similar effects under this new specification.[25]

Of course, we must be careful not to dismiss the role of racial attitudes on the basis of this relatively slender evidence. The measures of racial attitudes, while useful, leave much to be desired both in terms of coverage of areas and reliability for a given area. Nevertheless, evidence for a central role of racial attitudes in explaining regional differences in employment discrimination or altering our understanding of the effects of other factors cannot be adduced from this analysis.

Conclusion

In this article we have shown that metropolitan areas in the Northeast and the Midwest are characterized by higher levels of racial inequality in employment than metropolitan areas in the South and West. We also have shown that a number of theoretically relevant metropolitan characteristics predict area variation in racial employment inequality well and that regional differences in employment inequality are closely tied to regional differences on these metropolitan characteristics. Specifically, our analysis suggests that greater employment inequality observed in the Midwest and Northeast can be attributed to the lower economic growth, larger firm size, and higher union membership found in these regions compared to the South and West.

The finding that employment inequality is greater in the Northeast and Midwest is interesting because it contrasts with previous research focusing on other important indicators of racial inequality. Analyses of racial inequality in education, occupation, and income consistently document greater inequality in the South.[26] We can only speculate why interarea variation in racial employment inequality follows a different logic. Education differences are likely to be the function of racial dynamics in the funding and operation of school systems, factors that may not be germane to hiring dynamics. Occupation and income inequality may be lower in the North than the South because unions and the internal labor markets associated with large firms may provide protection against wage discrimination for employed workers. Unions and large firms may thus reduce racial inequality among workers who obtain jobs.[27] However, these protections may perversely intensify racial inequalities in employment by increasing the exclusion of minorities from employment in the first place.

In any event, at least one other important indicator of racial inequality — namely residential segregation — varies across regions according to the pattern observed here for employment inequality. Massey and Denton (1987, 1993) found that levels of white-black residential segregation were lower in the South and West and higher in the Northeast and Midwest (labeled North Central in their tables). This result also been reported by Farley and Frey (1994). Another parallel between our analysis and these analyses is that they both present evidence that residential segregation tends to decline in areas that experience strong economic growth (which is accompanied by growth in population and housing stock). Specifically, Massey and Denton found that employment growth had a positive effect on residential contact between whites and blacks and a negative effect on residential dissimilarity between blacks and whites. Similarly, Farley and Frey report that recent growth in housing stock has a negative effect on residential dissimilarity. The strong parallel between our findings and their findings in this regard provides further confirmation that a simple cultural explanation (focusing on prejudice) for racial inequality is likely to be an insufficient explanation of interregional variation in racial inequality.

A more complete explanation of differences in the regional patterns for various dimensions of racial inequality is needed. Future analyses should consider multiple dependent variables to determine whether regional differences in racial inequality in education, occupation, and income are simply subject to different determinants or whether their variation across areas can be understood

within a general framework that also accounts for area variation in employment inequality and residential segregation.

We hope that this article will help stimulate further consideration of the regional and area differences in racial opportunity. Regional and other interarea variation in racial inequalities has been somewhat neglected in the literature in recent decades. Theoretical perspectives such as the human capital and status attainment traditions have emphasized the labor supply side of stratification processes. They have focused attention on the characteristics individuals bring to labor markets and thus on the role of group differences in education and related resources in shaping inequality. Insights from these perspectives are important and they contribute to our understanding of inequality. However, inordinate focus on the effects of individual-level characteristics can sometimes obscure the fact that important macro patterns are there to be observed in the analysis of racial inequality.

These patterns suggest contextual effects operating in labor markets, regions, the state, and other macro units. Understanding the effects of employer practices, state policies, union strength, aggregate labor demand, and other factors shaping the nature of labor demand and its expression ultimately requires examination of macro empirical patterns. Comparative studies of inequality in regions and metropolitan areas provide one analytic tool that can be used to pursue these issues. Studies using other macro units (e.g., firms and organizations) also can be fruitful, although data are often less readily available. The results presented here provide additional evidence suggesting that demand-side factors are particularly important in the study of racial and ethnic inequality where individual outcomes are dramatically shaped by larger economic and political forces ranging from discrimination to economic growth.

Notes

1. These are the metropolitan areas for which detailed tabulations of employment status by age and sex are published for blacks.

2. Thus, in the typical city in the Midwest and Northeast whites' odds of employment are about 3.1 times as great as blacks' odds of employment, whereas in the typical city in the South and West it is only about 2.3 times as great.

3. It is important to remove the institutional and military populations from the calculation of employment-population ratios. Institutional populations (e.g., inmates of prisons) and military populations can have dramatic effects on employment-population ratios, yet their employment status does not reflect local labor market opportunities. Moreover, these populations do not necessarily originate in the local area and thus no simple relationship between local opportunities and the relative size of institutional and military populations can be assumed.

4. That is, $(W_e/W_n)/(B_e/B_n)$ where W_e is the number employed for whites, W_n is the number not employed for whites, B_e is the number employed for blacks, and B_n is the number not employed for blacks (all counts are for civilian, noninstitutional males 25-59 years old).

5. In contrast, the major alternative measure of employment inequality — the white-black difference in employment rates — is not well suited for regression analysis because standard OLS assumptions of linearity in relationships and normal distribution of the error terms are violated for these dependent variables (Hanushek & Jackson 1977). As is well known, these violations are nontrivial because they can lead to bias in estimates of causal effects and invalid tests of statistical significance (Aldrich & Nelson 1984). These potential problems are avoided

when employment differentials are modeled in terms of the log-odds and relative log-odds (Aldrich & Nelson 1984; Hanushek & Jackson 1977).

6. We are careful not to overemphasize this point, as the racial difference in employment rates can be a useful measure of employment inequality in some situations. Fortunately, it is highly correlated with the relative log-odds ratio in the our data ($r = 0.90$) and it describes a similar pattern of interregional variation in racial employment inequality.

7. The census sample records are drawn at the household level and the sampling rate may vary across small areas within the metropolitan area. The fraction of total persons represented in the sample data for a metropolitan area thus varies but rarely falls outside the range of 15 to 20%. (For further details see 1980 Census of Population, Volume 1 — Characteristics of the Population, Chapter D — Detailed Characteristics, Appendix D.)

[a] SMSAs containing conurbations, such as Dallas-Ft. Worth, have been shortened for space to the name of the first city, for example, Dallas.

8. Four cities — Hartford, Connecticut; New Haven, Connecticut; Raleigh-Durham, North Carolina; and Columbus, Ohio — are excluded because of missing data on independent variables used in the regression analyses.

9. Non-Hispanic whites are not tabulated directly, since the census category "whites" includes the Spanish origin population. We obtained data for non-Hispanic whites by subtracting nonwhite groups and Spanish origin from the total as appropriate. One minor problem with this procedure is that blacks of Spanish origin may be subtracted twice. However, we can find no evidence that this ever distorts the employment patterns for non-Hispanic whites in any significant way.

10. We use the median and the interdecile range to describe central tendency and dispersion for the relative odds ratios because distributions of odds ratios tend to be right skewed, rendering means and standard deviations inappropriate for descriptive statistics.

11. Many variables that are important determinants of inequality (e.g., mode of economic organization, nature of the political order, etc.) are simply not relevant for the task at hand because they are effectively constants across regions and metropolitan areas of the U.S. and therefore cannot account for regional differences in inequality.

12. Of course, this is an oversimplification since the investment theory that undergirds human capital theory implies that group differences in investments in education will be shaped by group differences in returns to education in the labor market.

13. Whether race is in fact a reliable proxy for such unmeasured productivity characteristics is an empirical question. What is clear, however, is that under conditions of slack labor demand, statistical discriminators will not necessarily suffer from ranking potential employees on the basis of ethnicity and may potentially gain. For example, unless race is inversely associated with unmeasured productivity characteristics, employers who use race as a tie-breaker to rank applicants with otherwise similar qualifications will at worst obtain employees who are no less qualified than those hired by nondiscriminating employers.

14. We currently are undertaking studies of mismatch effects based on detailed data on job and residential locations. However, our analysis will be limited to about a dozen cities due the limited availability of the relevant data and the cost of performing each within-city analysis.

15. An alternative based on years of schooling completed (estimated from category midpoints) proved less effective.

16. Conceptually, this is an attractive formulation because, unlike the more commonly used ratio of mean education, it is "symmetrical" in depicting relative advantage to whites and blacks (Fossett & South 1983). This can be important in samples where advantage sometimes favors blacks and sometimes favors whites. In our sample, however, educational inequality always favors whites and as a result the two measures are highly correlated ($r > 0.99$). Thus, analyses using the ratio of mean education to measure educational inequality yield identical substantive results.

17. We also examined unemployment rates. This had an effect similar to population growth, but the effect was less important and less robust than the effect of population growth.

18. We also considered state-level unionization estimates developed by Kokkelenberg and Sockell (1985). They produced virtually identical results. This is not surprising, since their correlation with the state-level estimates we used exceeded 0.97.

19. Systematic bias would be introduced by this measurement strategy only if MSA-specific deviations from state unionization scores were correlated with other variables in the analysis or with other potentially important but omitted variables.

20. That is, the expected black representation in the labor force based on the occupational mix is given by $\Sigma O_i P_i$ where O_i is the proportion of the labor force in the metropolitan area in occupation i and P_i is the percentage black in the occupation at the national level.

21. For example, the expected employment-to-population ratio for blacks in a given metropolitan area was given by $\Sigma A_i P_i$ where A_i is the proportion of blacks in the metropolitan area in age group i and P_i is the percentage employed for blacks in age group i at the national level.

22. For example, average population growth for metropolitan areas in the South was 23.087. This deviates from the national average of 15.292 by 7.795 points. The unstandardized regression coefficient for population growth reported in Table 2 was -0.00486. Multiplying 7.795

by -0.00486 yields -0.03788, which is the contribution of population growth to the South's deviation from the national average for the relative log-odds of employment inequality. This represents 32.88% of the observed regional deviation from the national average for inequality of -0.11522. That is 32.88 = 100.0 * -0.03788 / -0.11522. (Note the calculations reported here are based on numbers that are more precise than those reported in the tables. Performing the same calculations using the reported numbers will introduce rounding error.)

23. We are indebted to K. Jill Kiecolt who generously provided us with these data.

24. Individual-level factor analysis of the items in the racial tolerance scale yielded a single-factor solution. Cronbach's alpha is 0.66.

25. In fact, the metric effects (i.e., the unstandardized regression coefficients) of unionization, population growth, educational inequality, and occupational mix increase under this specification.

26. The pattern for employment inequality in our study cannot be attributed to an unusual sample. We examined data on racial inequality in aggregate attainments in education, occupation, and family income for metropolitan areas in our sample. As reported in previous studies, the South was characterized by higher levels of inequality for these indicators.

27. Relative to this point, it is worth noting that studies of occupational inequality focus on the employed population or the experienced civilian labor (without regard for employment status). Similarly, studies of income inequality often focus on comparisons involving persons who are employed or even employed full-time and year-round. Cotton (1989) has shown that analyses focusing on per capita income may yield decidedly different results.

Composition of the Workplace and Psychological Well-Being: The Effects of Tokenism on America's Black Elite*

PEGGY A. THOITS, *Vanderbilt University*
HOWARD F. TAYLOR, *Princeton University*

Abstract

Kanter's theory of proportional representation suggests that tokens should experience more work stress and psychological symptoms than nontokens. We examine the effects of proportional representation by race and by gender on work stress and symptoms. Data come from structured personal interviews with a disproportionate stratified sample of elite black leaders in the U.S. (N = 167). Consistent with expectations, analyses showed that numerical rarity by race and by gender significantly increased symptoms of depression and anxiety, respectively. Numerical rarity by race significantly increases "token stress" (e.g., loss of black identity, multiple demands of being black, sense of isolation, having to show greater competence) and a high degree of gender tokenism increases role overload. Some, but not all, of the total impact of proportional representation is mediated through work stressors since these stressors are themselves directly associated with higher psychological symptoms.

Numerical representation is an influential structural characteristic within most formal work organizations. Research suggests that minority-group size affects attitudes, achievement, and the frequency and quantity of interpersonal contact between majority and minority group members (Izraeli 1983; Konrad, Winter & Gutek 1992; South et al. 1982; Toren & Kraus 1987). Most of this research draws upon Kanter's (1977) theory of proportional representation, which argues that individuals who occupy token positions in their work settings experience three sources of stress: performance pressures, boundary heightening, and role entrapment.

* *The research reported here was supported by a grant from the Cornerhouse Fund, New York, NY.* *Direct all correspondence to Pamela Braboy Jackson, Duke University, Department of Sociology, Box 90088, Durham, NC 27708-0088.*

 Social Forces, December 1995, 74(2):543-557

There are three limitations to this research that we wish to address in this study. First, the hypothesis that proportional representation determines these distinct sources of work stress has not been systematically examined. Second, studies generally focus their attention on gender tokens. As a result, the implications of Kanter's hypothesis for other underrepresented groups have been neglected. And third, studies concentrate on tokens within single occupations without providing a general view of the effects of minority-group size on token experiences across work settings (see Wharton & Baron 1987 for an exception).

The purpose of this study is to examine the relationship between proportional representation and work-related difficulties. Although Kanter (1977) focuses on the consequences of particular work experiences for tokens' job performance, we argue that these stressors should affect tokens' psychological well-being as well. Relationships are examined using a sample of men and women drawn from the black leadership elite in America. Our extension of Kanter's theory should lead to a more comprehensive understanding of the ways in which the structure of relationships within the work setting can affect individual well-being.

Kanter's Theory of Proportional Representation

Discussion of the effects of differences in proportional representation within collectivities is not unique to Kanter. Hughes (1944, 1946, 1958) described the potential perpetuation of status conflict based on stereotyped expectations for behavior, highlighting the particular dilemmas faced by women and blacks who enter male and white occupations, respectively (also see Jackson 1962). Taylor and her colleagues (Taylor & Fiske 1975; Taylor et al. 1978) have focused on the evaluation of numerical minorities in white male-dominated groups. Other observational studies on numerical distinctiveness have been conducted (see Segal 1962; Wolman & Frank 1975; Yoder & Sinnett 1985) and currently the literature on the impact of proportional representation on individual group members is growing (e.g., Abrams, Thomas & Hogg 1990; Alexander & Thoits 1985; Macke 1981; Ruble & Higgins 1978; Spangler, Gordon & Pipkin 1978; Wharton & Baron 1987; Yoder 1994). The area of inquiry is not new, but Kanter provides a useful theoretical framework for it. Her emphasis on the sex composition of the group is important, but it is her elaboration of the stress produced by differences in status characteristics and tokens' reactions to these problems that guides our inquiry here.

According to Kanter (1977), work groups can be characterized as uniform, skewed, tilted, or balanced in proportional representation. Uniform groups are homogeneous; all members hold the same master statuses (e.g., white males). The ratio of majority to minority group members in such groups is 100:0. Stress due to differences in observable master status characteristics is absent in these work settings. In skewed groups, majority group members far outnumber minority group members. Kanter suggests ratios of majority to minority group members ranging from 99:1 through 85:15. She refers to majority group members as "dominants" and minority group members as "tokens" in skewed

groups. Those in numerical majority are assumed to control the group and its culture; tokens have very little power in these situations. Tokens are "often treated as representatives of their category, as symbols rather than individuals" (Kanter 1977:208). Tilted groups represent less extreme distributions. Kanter suggests ratios from 84:16 to 65:35, where dominants are still the majority and tokens still the minority. However, due to greater numbers, minority group members are one another's potential allies, can form coalitions, and can affect the culture of the group. As a result, Kanter hypothesizes that minority group members do not experience as much stress as those in skewed groups. Finally, in balanced groups, proportions range from 64:36 to 50:50. Culture and interaction, she argues, become balanced between majority and minority subgroups. In this situation, individual outcomes depend upon structural and personal factors related to the group member rather than group composition per se.[1]

According to the theory of proportional representation, tokens in skewed groups are the most vulnerable to lower levels of emotional well-being from three sources of stress. One discussed by Kanter (1977) is *performance pressure*. Because their "differentness" is highly visible, tokens feel that they are always under scrutiny. Further, because they are symbolic representatives of their "type," tokens experience added pressure to perform well, since this may determine future opportunities for other individuals in their social category. Tokens perceive that their performance ratings are based at least in part on their master status characteristics and not their actual achievements on the job. Thus, tokens may have to put in extra effort to have their achievements noticed. One response to performance pressure is to overachieve; another is to avoid calling attention to oneself or one's accomplishments (and thus potentially to be perceived as less competent or underachieving).

The second source of stress, *boundary heightening*, results from majority group members' tendencies to exaggerate their own commonalities as well as their differences from tokens. Tokens are repeatedly reminded of their difference through jokes, interruptions, exclusion from informal activities, and various "loyalty tests." As responses, tokens can either remain socially isolated or present themselves as exceptions to their category in order to become accepted insiders.

The third source of stress, *role entrapment*, involves typecasting by dominants. Tokens' behaviors are assimilated into existing cultural stereotypes of women (or blacks). Dominants' stereotyped assumptions and mistaken attributions force tokens to play limited and caricatured roles in the organization (e.g., for women, "mother" and "seductress"). Those who resist stereotyped roles are "trapped in a more militant stance than they might otherwise take" (Kanter 1977:236). Either way, "the personal consequence for tokens, of course, is a certain degree of self-distortion" (984).

We assume (as does Kanter) that performance pressures, boundary heightening, and role entrapment are experienced as stressors, i.e., as ongoing difficulties on the job that require behavioral readjustments. Further, tokens' adaptive responses — working harder or "laying low" and thereby suffering lack of recognition, accepting social isolation or turning against one's own (and thus, to some extent, oneself), playing stereotyped roles or combating stereo-

types — are likely to be stressors as well. Consequently, we expect token members in skewed groups to report higher levels of these stressors and of psychological symptoms than those in tilted, balanced, and other groups in which their "type" are the majority.

Kanter's work focused on the situations facing token women in sales management positions and male/female interaction patterns within a large industrial organization. We assume that the dynamics of interaction between "tokens" and "dominants" will be similar across work contexts, at least for leading professionals, government administrators, and chief executives (on whom we focus our analysis here). Tokens are identified by ascribed characteristics (i.e., gender, race, ethnicity). Attached to these characteristics are sets of secondary and informal assumptions about the culture, competence, and behavior of the status occupant. Thus, any interaction will be altered because attention is directed to the master status characteristic or the stereotypes informally attached to the status rather than to the individual's ability to perform a specific task (Hughes 1944; Kanter 1977). In this article, we focus on work stressors associated both with racial and gender tokenism.

Data and Methods

The data for this study come from a research project directed by the third author at Princeton University in 1983. The project was to investigate the network structure of America's black leadership. The primary goals of the study were to collect systematic background information on black elites, to examine the structure of the network links among these leaders, and to describe variations in the political and policy attitudes of the group. Structured personal interviews also elicited information on the gender and race composition of respondents' workplaces, occupational stress, coping responses, and symptoms of psychological distress. There were 167 respondents in the sample.

SAMPLE

To obtain a sampling frame of America's national black leaders, several population lists were compiled. First, institutional sector lists were developed (see Taylor 1992 for a detailed annotation of sources for each institutional sector). Sectors included major executives in both predominantly white and predominantly black businesses, then-current black mayors of major cities (and some former mayors), then-current black members of the U.S. Congress, black federal judges, high-ranking military officers, heads of predominantly black voluntary and civil-rights organizations, black heads of major philanthropic foundations, major media personalities (including columnists, correspondents, editors of major magazines, editors of black newspapers in large cities, entertainers, and athletes), high-ranking labor union officers, major civil service officials, and high-ranking Democratic, Republican, and independent party officers. Other listings included presidents of predominantly black colleges and universities, nationally prominent ministers, scholars and educators, writers and literary figures (intellectuals), and wealthy blacks.

Second, blacks in *Who's Who in America* (WWA; 1982) were enumerated. Because WWA does not indicate individuals' race or ethnicity, *Who's Who among Black Americans* (WWBA; 1980) was used as a cross-check for race. WWBA is by far the longest source list of prominent blacks in the U.S. (17,000 names were included in the 1980-81 edition). There were 960 names common to the two sources.[2] These names were supplemented by lists of national "influentials" published by *Ebony* magazine periodically since 1963 and yearly since 1971.[3] Those names not already on the WWA/WWBA list were added to it.

The WWA/WWBA list was compared to the institutional sector lists; all names on the WWA/WWBA list that did not appear in the institutional sector lists were added to the appropriate institutional listing. Generally, disproportionate (equal frequency) stratified sampling by institutional sector was employed (15-20 persons were drawn from each sector list), with random sampling within sectors. However, *all* black members of the U.S. Congress in 1984 and black heads of major philanthropic foundations were purposively included, given the small number of such individuals in each category. A list of 260 potential respondents resulted from these sampling procedures.

The response rate in the study was 70.5% ($N = 167$), excluding those who, between the time of sampling and contact for interview, had died, moved from the U.S., or were unreachable for other reasons ($N = 23$). This response rate is comparable to rates obtained in other major studies of elites, which range from 40% to 80%, with 60% to 70% being modal (Taylor 1992). The majority of respondents were interviewed by black interviewers.[4]

Table 1 reports the background characteristics of respondents. The majority are middle-aged, male, married, highly educated (95% are college graduates, 63% have advanced degrees), report median family earnings of $82,000 per year, and are in a wide range of prestigious occupations.[5]

Measures

PSYCHOLOGICAL DISTRESS

Abbreviated symptom scales from the Johns Hopkins Symptom Checklist were used to assess depression and anxiety. For brevity, items were selected if they had high factor loadings on depression and anxiety (Derogatis et al. 1971) and also matched symptom items included in the National Survey of Black Americans (Jackson 1979). Exploratory factor analyses showed that these items formed two factors in this sample. Depression was indicated by the sum of four items: "In the past week, how often did you feel down or depressed, feel hopeless about the future, lack enthusiasm for doing anything, feel lonely?" Cronbach's alpha for this scale was .75. Anxiety consisted of three items: feel tense or keyed up, feel nervous, have your heart pound or race when you were not physically active ($\alpha = .77$). Responses for these items ranged from 1 = never to 5 = very often.

TABLE 1: Descriptive Characteristics of Black Elites

Variable		N
Age		158
Mean age	54.6	
Median age	53.0	
Gender		167
Percent male	76.6	
Marital status		161
Percent married	77.0	
Education		152

PROPORTIONAL REPRESENTATION

Two questions assessed occupational group composition for race and for gender. "On a typical work day, do you work with people all of whom are black (female), most of whom are black (female), about half of whom are black (female), most of whom are white (male), all of whom are white (male) except you, or what?" Possible responses were coded: 5 = all are black (female);

4 = most are black (female); 3 = about half are black (female); 2 = most are white (male); 1 = all are white (male) except respondent. Follow-up questions asked, "About what percent would you say are black (female)?" These questions yielded both *ordinal* and *continuous percentage* indicators of black and female proportional representation. As a third measure, continuous percentages were collapsed using Kanter's suggested cut points, distinguishing skewed (1-15%), tilted (16-35%), and balanced (36-50%) groups (which we refer to below as "Kanter's cut points"). For all three indicators of proportional representation, lower values indicated situations in which whites (or males) are numerically dominant, higher values indicated black (or female) numerical dominance in the workplace. For regression analyses, for women respondents only, the percentage of female representation in the workplace was subtracted from 100 to yield the percentage of male representation. Thus, in regressions, the continuous gender percentage measure becomes the percentage of persons in the workplace of the *opposite gender* from the respondent (for both male and female respondents).

A majority of respondents reported working with mostly white and mostly male coworkers. The ordinal measures and Kanter's cut points placed 55-58% of the respondents in white-dominated groups (i.e., in skewed and tilted groups). About 46% of the respondents were in male-dominated workplaces according to the ordinal measures and 50% according to Kanter's cut points. Correlations among the three measures of proportional representation by race were quite high.[6] Given the consistency among these measures, we use the continuous percentage measure below in regressions.

A weakness of these proportional representation questions is their failure to distinguish explicitly between coworkers and clients. Respondents might be including the percentage of black (or female) clients with whom they come into contact each day. However, Kanter (1977) quite clearly states that the interpersonal dynamics that she discusses (performance scrutiny, boundary heightening, role entrapment) occur in contacts with clients as well as colleagues. Consequently, the lack of specificity in these questions should not be a serious drawback and may reflect the realities of relative numerical contacts in the workplace.

WORK STRESSORS

Respondents were asked if their work involved any of 16 pressures. These items included problems identified by Kanter: scrutiny, performance pressures, nonacceptance, and social isolation.[7] Several items tapped another potential stressor not discussed by Kanter, feelings of overload. Tokens presumably are more likely to be asked by their institutions and more generally by their public to serve as symbolic representatives of their "type" on additional committees, on panels, in policy sessions, and so forth. Consequently, tokens should experience multiple demands due to being black, have more demands made on their time in general, and have difficulties juggling their work and private lives.

Respondents indicated whether they experienced each pressure on the job (0 = no, 1 = yes), and if so, how much this pressure bothered them (1 = not at all, 2 = somewhat, 3 = very much). The frequency distributions of how much the pressure bothered them were bimodal, with 1 and 3 most frequent. Consequent-

ly, we retained dichotomous indicators for each work stress item (coded 0 = problem is not experienced, 1 = problem is experienced).

Exploratory factor analyses suggested five types of work stress. They included *scrutiny*: scrutiny by colleagues and public scrutiny; *nonacceptance*: experiencing discrimination, value conflicts, nonacceptance by whites, and nonacceptance by blacks; *token stress*: loss of black identity, multiple demands of being black, having to demonstrate more competence than peers, and a sense of isolation; *interpersonal conflict*: hostility from others, political infighting, and conflicting demands from various groups; and *role overload*: too many time demands, juggling private and work life, and too many responsibilities. Items composing each factor were summed as indices of each type of work stress. Because occupations differ greatly in structure (e.g., some jobs involve public scrutiny but not scrutiny by colleagues), we view these work stress measures not as scales but as indices, i.e., as sums of experienced work problems, grouped by type (Heise 1974).

It should also be noted that these questions tap individuals' subjective perceptions of occupational stressors rather than objective conditions of work. Thus, there may be some confounding of perceived work stress with individuals' psychological symptoms (e.g., highly depressed respondents might perceive more sources of occupational stress). We assume here that these successful, highly influential respondents are able to report fairly accurately on the stressors they encounter in their professional lives, but the possibility of reverse causality cannot be dismissed. See Appendix for correlations between work stressors and psychological symptoms.

Background variables include age (measured in years), gender (0 = male; 1 = female), marital status (0 = unmarried; 1 = married), education (measured in years), income (measured in thousands of dollars), and occupation (four dummy variables representing businesspersons, academics, entertainers, and "other" leaders; with politicians as the omitted comparison category).[8]

Results

TOKENISM AND PSYCHOLOGICAL DISTRESS

We expected black leaders who are outnumbered by whites in their work situations to exhibit higher levels of distress than those in balanced situations and situations in which blacks outnumber whites. Similarly, we expected men and women who are outnumbered in their workplaces by the opposite sex to have higher symptom scores than those who are surrounded by equal or greater numbers of the same sex. To examine these hypotheses, we regressed depression and anxiety scores on degree of racial and gender tokenism, holding background variables constant. The results from these baseline models show that our expectations were generally substantiated. As shown in panel A of Figure 1, the degree of race tokenism is marginally significantly related to higher depression scores, while high opposite-gender representation in the workplace is significantly associated with greater anxiety. Squared terms for race and gender representation were then added to each equation to check for possible curvilinearities. Curvilinearity was found in the relationship between

black representation and anxiety (the beta for percent black was 4.83, $p < .10$; the beta for percent black squared was -6.28, $p < .05$), indicating lower symptoms of anxiety at the highest levels of black representation (not shown in Figure 1).[9]

TOKENISM AND WORK STRESS

According to the theory of proportional representation, blacks in white-dominated workplaces, men in female-dominated workplaces, and women in male-dominated workplaces should report more work stressors than others whose colleagues and clients share similar master status characteristics. To test this hypothesis, each work stress index was regressed on the proportional representation measures, the other indices of work stress, and the background control variables. The left half of panel B in Figure 1 shows that race proportionality has a significant effect on token stress. Elites who work in predominantly black work settings report fewer problems with token stress than elites in work settings that are not predominantly black, a finding consistent with Kanter's (1977) hypothesis. However, proportional representation by race is not associated with other kinds of work stresses (scrutiny, nonacceptance, interpersonal conflict, role conflict). Elites in workplaces dominated by members of the opposite gender, on the other hand, report significantly more problems with role overload than their peers. Again, however, representation by gender is unrelated to other types of work stress. Thus, we found only partial support for Kanter's general hypothesis that same-status representation in the workplace affects the experience of work problems. That support is limited to certain status compositions of the workplace and particular kinds of occupational problems.[10]

TOKENISM, WORK STRESSORS, AND PSYCHOLOGICAL DISTRESS

The final step in the analysis examined the relationships among proportional representation, work stressors, and psychological symptoms. Does the experience of specific work stressors explain the higher depression and anxiety scores of elites who are outnumbered by whites and the opposite sex, respectively? Depression and anxiety scores were regressed on the proportional representation measures, the five types of work stress, and the background control variables. The results are presented in the right half of panel B, Figure 1. As shown, the degree of race tokenism continues to be a significant predictor of depression, even when token stress and other work stressors are controlled. Similarly, the direct effect of opposite-gender representation on anxiety remains statistically significant when role overload and other stressors are held constant. Again we see that proportional representation in the workplace has significant impacts on psychological well-being, as initially hypothesized. Moreover, these impacts are both direct and indirect through specific work stressors. Elite blacks who are outnumbered by whites report more token stress and token stress, in turn, increases depression. Elite men and women who are outnumbered by the opposite gender report more role overload and role overload, in turn, increases both depression and anxiety.[11] When squared terms for percent black and percent opposite-gender representation were added to these equations, again the inverse U-shaped relationship between percent black and anxiety appeared (the

+ $p < .10$ * $p < .05$ ** $p < .01$

B for percent black was 4.23, p = ns; the *B* for percent black squared was -6.39, $p < .05$), indicating lower anxiety at the highest levels of black representation, net of work stressors (not shown in Figure 1).[12]

Discussion and Conclusions

Kanter's (1977) theory of proportional representation suggests that individuals who hold token positions will experience distinct problems at work compared to peers working in settings that are balanced in status composition or dominated by members of the same gender or race. Kanter's analysis also implies that tokens should experience greater symptoms of psychological distress due to work pressures. This article provided an empirical test of these hypotheses within a sample of black elite leaders.

We found limited support for the argument that a variety of work stressors are associated with proportional representation. Consistent with the theory, the higher the black percentage in the work setting, the fewer problems elites

reported due to the salience of their black identity (specifically, loss of black identity, multiple demands of being black, having to demonstrate more competence than peers, and a sense of isolation). In addition, high opposite-gender representation was associated with experiences of role overload. However, problems due to scrutiny, nonacceptance, and interpersonal conflict did not vary with the racial or gender composition of the workplace. It appears that proportional rarity produces a more restricted range of difficulties than Kanter suggested, at least within this elite sample.

The finding that racial tokenism increases experiences of token stress is consistent with the larger theoretical and empirical literature on gender tokenism (Blau 1977; Kanter 1977; Macke 1981; McGuire et al. 1978), although our gender tokens did not report an excess of these problems (perhaps because a number of the work stress items were worded in ways that referred to racial and not gender identity). Furthermore, both men and women in situations dominated by the opposite sex experienced role overload. This finding contrasts with research that suggests that male tokens are not exposed to the same stressful work conditions as female tokens (Blau 1977; Gutek 1985). We suspect that women and men who are numerically rare in their work settings may be finding themselves in a position where they are often asked to represent their gender "type."[13]

Although the range of difficulties reported by elite tokens was more delimited than expected, these difficulties nevertheless had significant psychological consequences (as did proportional representation itself). Elites experiencing the pressures associated with token status or role overload suffered higher depression or anxiety, respectively. Even when these sources of work stress were controlled, workplace composition directly affected individuals' psychological symptoms. In workplaces dominated by blacks, black elites' symptoms of depression (and anxiety) were lower. In workplaces dominated by the opposite gender, elites' symptoms of anxiety were higher.

In sum, proportional representation by race and by gender did affect elites' psychological well-being both directly and indirectly through work stress. The direct effects of proportional representation on symptoms are important because the phenomenon of tokenism transcends the work setting and influences the dynamics of group interaction more generally. The findings also raise the question of how race and gender tokens cope with the work stressors created or exacerbated by their status. Perhaps effective sources of social support can alleviate the negative impact these particular stressors have on psychological well-being. These issues await future study.

The limitations of this study must, however, be underscored. This was a very select sample of black leaders. Individuals in elite positions represent 1% of the U.S. population and black elites constitute a small fraction of this group. Therefore, the results from this study cannot be generalized beyond such elites. Furthermore, the large number of busy respondents for whom the key variables of interest were skipped is a concern. Finally, the data are cross-sectional, leaving open the possibility of alternative causal orderings of key variables (e.g., token elites may report more sources of work stress if they are depressed or anxious).[14] An important aspect of theory building, nonetheless, involves testing the applicability of the theory to various segments of the population. This

sample of eminent, successful blacks offered a unique opportunity to examine the relevance of Kanter's well-known theory of proportional representation. Additional research will be needed to verify that tokenism, with its accompanying occupational pressures, influences psychological well-being in the general working population. Future research should also explore how elites cope with stressful work conditions.

Notes

1. Kanter offers these ratios as tentative cut points and discusses the concept of "tipping point." Unanswered questions include: How many of a category are enough to change a person's status from token to full group member? When does a group move from skewed to tilted to balanced? We use her suggested ratios as qualitative cut points, but in recognizing that cut points might be set higher or lower, we also examine a continuous measure of proportional representation.

2. Because WWBA includes a large number of locally prominent leaders, it is not an appropriate population list of national influentials. WWA is a key source list because it includes not only government and business leaders but literary figures, academics, entertainers, and sports figures as well (Lieberson & Carter 1979). Our matched list of 960 names is very close to a rough statistical calculation that there are about 1,000 blacks in WWA, which can be derived from estimates in Lieberson and Carter (1979).

3. *Ebony* editors select each year's names. *Ebony* lists tend to overrepresent heads of fraternal organizations and underrepresent literary figures and academics (Henry 1981).

4. Interviews were in person and consisted of both structured and open-ended questions. The average interview lasted two and one-half to three hours (range 1 to 5 hours). Interviews occurred between September 1984 and the spring of 1987, with the majority of interviews completed by the summer of 1985. The response rate varied from sector to sector. Eighty percent of the 21 black members of Congress and 70% of 20 sampled military officers participated. Big-city mayors and federal judges were the most difficult to interview, with response rates of 30% and 45%, respectively, out of 20 in each category. Judges in particular cited the constraints of the law as reasons for refusal.

5. Approximately 30 respondents have missing data on the work stress and psychological symptom scales. Because a number of respondents were extremely pressed for time, interviewers were instructed in such cases to skip specific blocks of interview questions, including psychological distress, work stress, and coping items. Respondents for whom these questions were skipped are quite similar demographically to other respondents in the study. Most are older males (the average age is 55), highly educated (66% report an advanced degree), married (85%), and earn high incomes. Many of these respondents work in Congress ($N = 13$; 43%), suggesting that these politicians were probably the most pressed for time.

6. The ordinal measure of race representation is correlated with the continuous percentage measure at $r = .89$ ($p < .001$) and with the cut points measure at $r = .89$ ($p < .001$). Not surprisingly, the continuous version of the race measure is almost perfectly correlated with Kanter's cut points ($r = .99$, $p < .001$). Similarly high correlations were obtained among the gender indicators. Among men, correlations between the ordinal and interval measures of gender, the ordinal and Kanter measures, and the interval and Kanter measures are .86, .80, and .97, respectively. For women, corresponding correlations are .90, .85, and .98, respectively.

7. Indicators of role entrapment are not in the list; appropriate brief questions tapping this problem were hard to generate.

8. Respondents whose income was missing were assigned the median income category. In addition, there were 14 millionaires in the sample; one reported a net worth of just over 100 million dollars. The income of these respondents was recoded at $50,000 higher than the highest reported income to lessen the impact these outliers would have on our estimates. In

(11) Generalized distress											1.00	22.75	7.50	137

* p < .05 ** p < .01

terms of occupational category, politicians included members of Congress, political party officials, civil servants, mayors, civil rights leaders, labor leaders, and leaders of interest groups. Businesspersons included foundation heads, heads of financial institutions, and major executives. Entertainers included actors, athletes, and media personalities. Academics included intellectuals and college presidents. "Other" leaders were in religious and military positions.

9. We also explored the effects of "double tokenism," i.e., being outnumbered both by race *and* by gender in the workplace. Although we have suggestive evidence that double tokens experience higher symptoms of depression and anxiety, the number of these individuals was too small ($N = 17$) to enable meaningful analysis.

10. In each of the regression equations where work stress was the dependent variable, we also examined the impact of proportional representation, *excluding* the other indices of work stress. This approach failed to change the pattern of results reported in the body of the article, therefore, we present the full regression model which controls for other work stressors.

In addition, two interaction terms were added to the equations to assess whether the impact of group representation on work stress (and psychological well-being) differs by gender (i.e., gender*percent black; gender*percent opposite-gender). Only one interaction term was significant. Women who are in predominantly black workplaces report fewer problems with acceptance than other elites ($\beta = -2.01$, $p < .10$).

11. Results from all regression models are available upon request.

12. To further examine the nonlinearities in the effects of proportional representation on anxiety, we regressed anxiety on four dummy variables that indicated the intervals of proportional representation suggested by Kanter (see text), using the balanced group as the comparison category. According to these results, it would appear that the "tilted to black" (i.e., 65:35) category represents the point at which increases in representation begin to reduce anxiety. We would like to thank an anonymous reviewer for recommending this exploration.

13. As noted by one reviewer, this interpretation raises the possibility that the relationship between gender representation in the workplace and psychological well-being may be a gender effect. However, there was no significant relationship between gender and proportional representation. In fact, contrary to expectations, over half of the women work in settings that are either balanced in gender proportions or are predominantly female.

14. We did examine, however, the latter two models holding constant the depression and anxiety scores. The patterns reported in the body of the paper remained significant even under these conditions.

Hispanic Educational Attainment: The Effects of Family Background and Nativity*

ROGER A. WOJTKIEWICZ, *Louisiana State University*
KATHARINE M. DONATO, *Louisiana State University*

Abstract

We first examine the degree to which foreign birth explains the lower educational attainment of Mexicans and Puerto Ricans compared to whites. Although foreign birth is a partial explanation of group differences, family structure and parental education are more important explanatory variables. However, when we consider how the effects of nativity vary across Hispanic groups, we find that while U.S.-born Mexicans have higher educational attainment than foreign-born Mexicans, U.S.-born Puerto Ricans are no better off than foreign-born Puerto Ricans. We also find heterogeneity in the educational experiences of U.S.-born Mexicans. Those with foreign-born parents have higher educational attainment than those with U.S.-born parents.

Dramatic differences in educational attainment between Hispanic and non-Hispanic groups have persisted over the last 20 years. By 1991, only 61% of Hispanics 20 to 21 years old had completed high school compared with 81% of non-Hispanic blacks and 90% of whites (U.S. Department of Education 1992). Because education is a strong predictor of personal income, these differences contribute strongly to explanations of economic inequality between Hispanics and non-Hispanics.

The present study investigates two sources of the difference in educational attainment between Hispanics and non-Hispanics: family background and nativity. As we show below, Hispanics have fewer of the family background characteristics that lead to higher educational attainment. In addition, Hispanics are much more likely to be foreign born, a characteristic related to lower educational attainment. Our study examines the degree to which these differences in family background and nativity explain differences in educational

 Social Forces, December 1995, 74(2):559-574

attainment. We also investigate how the negative effect of nativity varies across Hispanic groups.

Previous Research

Strong influences on the educational attainment of Hispanics fall into two types: general and specific (Fernandez, Paulsen & Hirano-Nakanishi 1989). General predictors are important not only for Hispanics but for all race and ethnic groups and include family background factors such as socioeconomic status and aspects of family structure, such as absent parent, presence of a stepparent, and number of siblings.

Prior research on educational attainment has shown that parental education is a strong predictor of children's education (Featherman & Hauser 1978; Haveman, Wolfe & Spaulding 1991; Mare 1979). Parents with more education provide a home environment that supports and encourages the education of children, and they have more income available to finance education and related activities.

Other characteristics have been linked to low educational attainment, such as living in mother-only families (Krein & Beller 1988; McLanahan 1985), living in stepparent families (Astone & McLanahan 1991; Sandefur, McLanahan & Wojtkiewicz 1992; Wojtkiewicz 1993), and having many siblings (Blake 1989). Living with a single parent or stepparent means less available family income and parental time for the socialization, supervision, and control of children. Living with more siblings diminishes the amount of parental and financial resources available to each child (Powell & Steelman 1990).

Some predictors identify characteristics that are much more common among Hispanics than other groups: foreign birth, non-English language background, and short duration of U.S. residence. Studies have documented that proficiency in English lowers the likelihood that Hispanics drop out of high school (Bean & Tienda 1987; Fligstein & Fernandez 1985a, 1985b; Rong & Grant 1992; U.S. Department of Education 1992), whereas not living in the U.S. at the age of 14 raises the chance of dropping out (Rumberger 1983). In addition, foreign birth reduces the likelihood for Hispanics to graduate from high school (Bean & Tienda 1987; Fligstein & Fernandez 1985a, 1985b; Velez 1989). These effects arise because they are linked to lower competency in speaking and understanding English, which hampers academic achievement. They may also indicate educational experiences in countries where the quality of schools is lower, and where levels of final attainment are lower, than in the U.S.

Fernandez, Paulsen, and Hirano-Nakanishi (1989) investigated how these background factors contributed to the difference in educational attainment between Hispanic and non-Hispanic groups by estimating separate logistic regression models for each and then calculating probabilities of dropping out of high school. They found that the gap in educational attainment was reduced after controlling for differences between Hispanic and non-Hispanics in both general and specific characteristics.

A positive aspect of nativity found in other research was that U.S.-born children of immigrants had higher levels of educational attainment than

comparable children of U.S.-born parents (Fligstein & Fernandez 1985a, 1985b; Rong & Grant 1992; U.S. Department of Education 1992). In addition, Kao and Tienda (1995) found that while Hispanic children with foreign-born parents did not have higher grades, mathematics scores, or reading scores, they did have higher college aspirations.

Thus, in contrast to the steady increase that assimilation theorists predict for immigrant socioeconomic status over time, the reality is often quite different Immigrant educational attainment is not simply a product of duration of residence in the U.S.(Portes & Rumbaut 1990)[1]; it may reflect a set of motivations unique to immigrant parents (Fernandez, Paulsen & Hirano-Nakanishi 1989; Lieberson 1980). One consequence may be that children of immigrant parents have better educational outcomes than those of U.S.-born parents.

Present Study

Our analysis explores the degree to which family background and nativity explain the gap between Hispanics and non-Hispanics in educational attainment. Previous research has documented the important role of family background, and nativity is a characteristic that distinguishes Hispanics from other disadvantaged groups, such as blacks and Native Americans.

We begin with a bivariate analysis that shows that (1) educational attainment is related to family background and nativity and (2) family background and nativity are related to race and ethnicity. We then use logistic regression to examine the degree to which educational differences between Hispanics and non-Hispanics are explained by nativity and, subsequently, by other family background characteristics. In the analysis we consider four separate Hispanic groups: Mexicans, Puerto Ricans, Cubans, and other Hispanics. Because these groups are dissimilar in country-of-origin experiences, U.S. settlement patterns, and cultural expectations (Bean & Tienda 1987), we expect considerable variation in their educational attainment.

The next part of the analysis explores the degree to which the effect of nativity varies across Hispanic groups. We are especially interested in whether the effect of nativity differs between Mexicans and Puerto Ricans, who are U.S. citizens by birth and free to enter the U.S. Because Mexicans often enter the U.S. without legal documents (Donato 1994; Massey et al. 1987), illegal status may constrain their educational achievement. Thus, we expect a smaller negative effect of nativity for Puerto Ricans than for Mexicans.

In the final part of our analysis, we differentiate between persons of Mexican ancestry, who were U.S. born with U.S.-born parents, and those born in the U.S. with parents born in Mexico. We expect to replicate earlier studies that report that U.S.-born natives with foreign-born parents attain more education than those with U.S.-born parents. However, we are particularly interested in determining if this difference is due to underlying differences in family background.

Data and Methods

DATA

For this analysis, we use data from the National Longitudinal Survey of Youth. The survey is a national probability sample of men and women who were first interviewed in 1979 when they were between 14 and 21 years old and interviewed every year thereafter. To ensure representativeness and adequate sample sizes, the cross-sectional sample was supplemented with subsamples of groups typically with low representations in national surveys: minority groups, economically disadvantaged non-Hispanic whites, and persons in the military.

The survey is a rich source of information about the labor force and educational transitions that young adults make as they move into adulthood. In addition, it has an excellent response rate. Excluding the military subsample, 90.2% of respondents interviewed in 1979 were interviewed again in 1988 (Center for Human Resource Research 1991). For our purposes, we use the cross-sectional sample and the black and Hispanic supplemental subsamples from the 1979 through 1990 waves of the survey.

DEPENDENT VARIABLE

In this analysis, our dependent variable is high school completion, a key educational transition (Mare 1979, 1981). We are interested in explaining differences in high school completion between race and ethnic groups because having a high school degree provides the basic skills necessary for full-time employment; those who do not obtain a high school degree are much more likely to be in marginal jobs or unemployed. We measure high school completion by whether respondents completed 12 years of school by age 25. Those who had received General Equivalency Degree certificates without a high school diploma were classified as not having a high school degree.

INDEPENDENT VARIABLES

Our independent variables include race and ethnicity, nativity, family structure, socioeconomic status, and parents' nativity. We measured race and ethnicity using survey questions that asked respondents to identify their origin or descent. In cases where more than one origin was mentioned, we used the origin to which respondents reported identifying most closely. This process produced eight categories for race and ethnicity. In addition to blacks, Native Americans, Asians, and non-Hispanic whites, we identify four Hispanic groups: Mexicans, Puerto Ricans, Cubans, and other Hispanics. The latter includes persons with a variety of national origins. By Mexican, Puerto Rican, or Cuban, we mean those who are of Mexican, Puerto Rican, Cuban heritage either by birth or ancestry.

To create the nativity variables, we used information from respondents about whether they, or their parents, were born in the U.S. For those born in the U.S. or its territories, we were able to identify those of Puerto Rican origin who were born in Puerto Rico.[2] Because the survey did not ask the specific place of each parent's birth for those born in U.S. territories, however, we were unable to determine the nativity of the parents of Puerto Rican respondents.

We also include two variables that are closely related to nativity. One variable is whether a foreign language was spoken at home during the respondent's childhood. By including this variable in the analysis, we can determine the degree to which nativity captures the effects of weaker English language skills. The second variable is residence at the age of 14. Including this variable allows us to consider the extent to which the effects of nativity on graduation are due to growing up in countries where dropping out of school at young ages occurs more often than in the U.S. Because no precise measure of residence duration is in the survey, residence at the age of 14 also provides a rough control for the length of time respondents have spent in the U.S.

Finally, we also include parental structure and education and number of siblings in our models because these variables strongly affect educational attainment. Parental structure measures with which parents respondents lived at the age of 14. Parental education measures the educational level of either the mother or father, whichever was higher. We also include a variable for sex in our models to control for any sample differences between race and ethnic groups.

Descriptive Analysis

GRADUATION RATES

Our results are consistent with previous findings and show that Mexicans and Puerto Ricans have the lowest graduation rates (Table 1). Slightly more than half the Puerto Ricans in our sample were high school graduates, whereas 60% of Mexicans graduated from high school. Non-Hispanic whites and Asians were much more likely to graduate from high school (with completion rates over 80%), and about three-quarters of the Cubans, other Hispanics, and blacks completed high school.

The foreign born exhibited lower high school graduation rates than natives. Respondents living in homes where a foreign language was spoken had lower high school completion rates than those in homes without a foreign language. In addition, those living in the U.S. at the age of 14 had higher high school graduation rates than those not.

There were strong differences by family background in high school graduation rates. Those living in a single-parent or stepparent family were less likely to graduate than those living with two biological parents, and those with more siblings were less likely to finish than those with fewer siblings. Almost

all respondents with college-educated parents graduated from high school. In contrast, less than two-thirds of those with high school dropout parents completed high school.

DISTRIBUTIONS

Compared to non-Hispanic whites, Hispanic groups have consistently higher percentages with backgrounds that lead to lower educational attainment (Table 2). For example, Hispanics are much more likely than non-Hispanic whites to be foreign born. About 26% of Mexicans, 35% of Puerto Ricans, and 58% of Cubans were foreign born compared to just 3% of non-Hispanic whites.

On the whole, Hispanics were much more likely than non-Hispanic whites to live in a home where a foreign language was spoken. Nine percent of whites lived in such a situation compared to 92% of Mexicans, 96% of Puerto Ricans, and 97% of Cubans. Hispanics were also more likely than non-Hispanic whites to have lived outside the U.S. as teenagers. Ten percent of Mexicans, 7% of Puerto Ricans, and 7% of Cubans lived elsewhere at the age of 14, but only 1% of whites did so.

Puerto Ricans and Mexicans were more likely to experience disadvantageous family structures than non-Hispanic whites. For example, 37% of Puerto Ricans and 16% of Mexicans lived in single-parent families at the age of 14 compared to 10% of whites. While 31% of whites reported four or more siblings, almost two-thirds of Mexicans and more than half of all Puerto Ricans had large sibships. Moreover, the educational attainment of Puerto Rican and Mexican parents was also considerably less than whites. Only 16% of whites had parents who completed less than high school compared to 65% of Mexicans and 58% of Puerto Ricans.

Multivariate Analysis

ADDITIVE MODELS

Below we provide a formal test of the degree to which the higher proportion of Hispanics with disadvantaged background characteristics contribute to differences in graduation rates between Hispanics and non-Hispanic whites. We begin our examination in Table 3 by estimating three logistic regression models predicting whether respondents completed high school. Model 1 compares the likelihood of graduating from high school for Mexicans, Puerto Ricans, Cubans, other Hispanics, blacks, Native Americans, and Asians to that for whites, without controlling for other predictors. With the exceptions of Cubans and Asians, each of the race and ethnic groups have significantly lower chances of graduating from high school than whites, and Mexicans and Puerto Ricans are particularly disadvantaged.

In model 2 we consider the extent to which race and ethnic differences in high school graduation are due to differences in nativity. The effect of being foreign born on high school completion is negative and significant. The difference between Hispanics and non-Hispanic whites in high school graduation rates decreases because Hispanic groups have higher proportions of foreign

born, and foreign birth lowers chances of graduation overall. However, Mexicans, Puerto Ricans, other Hispanics, blacks, and Native Americans are still less likely than whites to graduate from high school after controlling for nativity.

Model 3 further explains inequality in high school graduation between these groups by controlling for other relevant factors. Except for foreign language spoken in the home, all other background variables significantly affect high school graduation. Residence at the age of 14 and parental education have particularly strong effects on high school graduation. Those who resided outside the U.S. at the age of 14 had much lower chances of high school graduation, whereas those with college-educated parents had higher chances. In addition, respondents from single-parent or stepparent families and those with more siblings were less likely to complete high school. Finally, consistent with previous research, women were more likely to finish high school than men.

Controlling for these background attributes reduces the race and ethnic differentials we observed in model 2. Blacks, for example, are comparable to whites in high school completion rates once background characteristics were controlled. Furthermore, differences between whites and Mexicans, Puerto Ricans, and Native Americans diminished, but these groups still had significantly lower chances of finishing high school than whites. These findings suggest that the lower high school graduation rates of Mexicans, Puerto Ricans, and Native Americans are due to variables other than those included in model 3.

When predicting high school completion net of background characteristics, the magnitude of the foreign-born coefficient declined by more than half. Therefore, part of the negative effect of being foreign born observed in model 2 was due to the greater likelihood that foreign-born respondents had background characteristics that lowered educational attainment. These include residing outside the U.S. at the age of 14 and having parents with less than a high school education.

In analysis not shown, we examined race and ethnic differences in chances of college graduation among those who had graduated from high school. These results showed that nativity did not have a significant effect on college graduation. Thus, nativity did not help explain the lower college graduation rates of Mexicans and Puerto Ricans compared to non-Hispanic whites. Race and ethnic differences in completing college were also not due to higher proportions of respondents living in a home in which a foreign language was spoken nor to living outside the U.S. at the age of 14. What we did observe, however, was that controlling family background attributes reduced race and ethnic group inequality in college completion. Consistent with previous findings, respondents were less likely to graduate from college if they were from single-parent or stepparent families, had many siblings, or had parents with low levels of education. Because children from Puerto Rican and other Hispanic families were more likely to have these attributes, the differences between them and non-Hispanic whites disappeared when these factors were controlled. However, Mexicans, blacks, and Native Americans remained less likely than whites to graduate from college, despite the narrowing of group differences.

INTERACTION BETWEEN FOREIGN BIRTH AND RACE/ ETHNICITY

So far, our analyses have assumed that the effects of foreign birth on high school graduation are the same for each race and national origin group. To test whether the effects of foreign birth are the same for all race and ethnic groups, the analysis in Table 4 considers the interaction between foreign birth and race/ethnicity. Building on model 3 in Table 3, we added interaction variables for foreign-born Mexicans, Puerto Ricans, Cubans, other Hispanics, blacks, and Asians. We did not add an interaction variable for foreign-born Native Americans because there were too few.

The first set of coefficients in Table 4 measures the difference in high school graduation rates between the U.S. born in each race/ethnic group and U.S.-born non-Hispanic whites. Only U.S.-born Puerto Ricans and Native Americans fared worse than U.S.-born whites in chances of high school graduation, and the Puerto Rican effect was notable in that its size was twice that for Mexicans.

The coefficient for the foreign born variable in Table 4 measures the difference between U.S.-born and foreign-born non-Hispanic whites. There was no significant difference. The last set of coefficients measures the difference between the U.S. born and foreign born for each race/ethnic group. Foreign-born Mexicans were significantly less likely to graduate from high school than U.S.-born Mexicans, while there was no difference between U.S.-born and foreign-born Puerto Ricans. In a statistical test not shown, both foreign-born Mexicans and foreign-born Puerto Ricans were found to be less likely to graduate from high school than U.S.-born non-Hispanic whites.

These interactions reveal a pattern of differences in high school attainment not visible in the additive models. Net of other variables, Puerto Ricans had lower chances of completing high school than whites. Whether born on the island or mainland, Puerto Ricans fared worse than whites, suggesting a unique effect of being Puerto Rican compared to other Hispanic groups. Foreign birth clearly matters for Mexicans. Foreign-born Mexicans had lower rates of high school completion than U.S.-born whites but U.S.-born Mexicans were no different from U.S.-born whites.

There are no differences for other groups. Neither U.S.-born nor foreign-born other Hispanics had lower high school graduation rates than U.S.-born whites. The same was true for U.S.-born and foreign-born blacks, and U.S.-born and foreign-born Asians.

EFFECT OF PARENT'S PLACE OF BIRTH

In this final section, we explore the effect of parental nativity on high school graduation. Because we lack data to measure the parental nativity of Puerto Rican respondents and have small sample sizes for other race and ethnic groups, we restrict this analysis to Mexicans. Table 5 divides U.S.-born Mexicans into three groups: (1) those with two parents born in the U.S., (2) those with only one U.S.-born parent, and (3) those with two foreign-born parents. In addition, we include a category for respondents who were foreign born and had foreign-born parents and a category for respondents for whom data were missing. We contrast each Mexican group with U.S.-born non-Hispanic whites.

* $p < .05$ (two-tailed test)

Table 5 shows that foreign-born Mexicans with foreign-born parents had significantly lower chances of high school graduation than U.S.-born whites. There is, however, diversity among U.S.-born Mexicans. Those with either one or both parents born in the U.S. have significantly lower chances of finishing high school than U.S.-born whites. Mexicans born in the U.S. to foreign-born parents, on the other hand, were more likely to graduate from high school than U.S.-born whites. We found in analysis not shown that the difference in high school graduation rates between U.S.-born Mexicans with foreign-born parents and U.S.-born Mexicans with U.S.-born parents was statistically significant. Therefore, although Table 4 documents that U.S.-born Mexicans had high school graduation rates comparable to whites, this finding masked a strong difference among U.S.-born Mexicans. Native-born Mexicans with both parents foreign born had significantly higher chances of completing high school than Mexicans with U.S.-born parents.

In analysis not shown, we examined differences between Mexican groups in their chances of graduating from college. Controlling for background factors,

TABLE 5: Logistic Regression of High School Graduation on Nativity of Respondent and Parents for Mexicans[a]

(N = 8,894)		

[a] The model controls for foreign language spoken at home, residence at age 14, sex, parental structure, number of siblings, and parental education and includes variables for interactions between race/ethnicity and nativity for other race/ethnic groups.

* $p < .05$ (two-tailed test)

U.S.-born Mexicans who had two U.S.-born parents were significantly less likely to graduate from college than whites. In contrast, U.S.-born Mexicans with foreign-born parents were as likely as U.S.-born whites to finish college. The difference in chances of college graduation between U.S.-born Mexicans with two U.S.-born parents and those with two foreign-born parents was statistically significant.

Thus, parental nativity plays an important role in determining the educational attainment of U.S.-born respondents. U.S.-born Mexicans with foreign-born parents have higher high school graduation rates than either U.S.-born Mexicans with U.S.-born parents or foreign-born Mexicans. They also have higher chances of graduating from high school than non-Hispanic whites. Our analysis of college graduation showed a similar pattern. U.S.-born Mexicans with foreign-born parents were more likely to graduate from college than U.S.-born Mexicans with U.S.-born parents.

Discussion

Using data from the National Longitudinal Survey of Youth, we investigated the educational attainment of Hispanics. One characteristic which we considered may explain the lower rates of educational achievement among Mexicans and

Puerto Ricans: their greater chances of being foreign born. Because foreign birth is related to lower rates of high school graduation, we examined whether the higher proportion of foreign born among Mexicans and Puerto Ricans would explain their lower educational attainment than non-Hispanic whites. In our analysis, we found that foreign birth converted to lower rates of high school graduation. However, neither foreign birth nor other family background factors fully explained the lower educational attainment of Mexicans and Puerto Ricans.

In an analysis of interactions we discovered a more complex pattern of effects on high school attainment than those reported in the additive models. Net of other factors, foreign-born Puerto Ricans were no different from U.S.-born Puerto Ricans; both groups had lower chances of high school completion than non-Hispanic whites. Foreign birth had a strong negative effect on high school completion among Mexicans, however. Although U.S.-born Mexicans were not different from non-Hispanic whites in their chances of completing high school, foreign-born Mexicans had much lower chances.

Thus, one of our key findings is that U.S.-born Puerto Ricans have high school completion rates lower than those of U.S.-born Mexicans. Note that lower high school completion rates for U.S.-born Puerto Ricans appeared when other factors such as language, residence at the age of 14, family structure, and parental education were held constant. This is consistent with findings from a growing body of research that documents the unique disadvantage of being Puerto Rican (see Cooney 1978; Tienda 1989; Tienda, Donato & Cordero-Guzmán 1992).

Finally, by differentiating Mexicans not only by their own place of birth but also by their parents' place of birth, we found important differences among U.S.-born Mexicans. While U.S.-born Mexicans with U.S.-born parents were less likely to graduate from high school than whites, U.S.-born Mexicans with foreign-born parents were more likely to graduate from high school than whites. These results suggest that immigrant parents may pass on higher levels of motivation to their children than do native U.S. parents, and in doing so, their U.S.-born Mexican offspring have higher educational attainment than the children of U.S.-born parents.

Our analysis, therefore, has uncovered some puzzling findings related to nativity that raise questions for future research. Researchers must address (1) why place of birth does not affect the high school completion rates of Puerto Ricans; and (2) why U.S.-born Mexicans with foreign-born parents are more likely to graduate from high school than either whites or U.S.-born Mexicans with U.S.-born parents.

Answers to these questions will require examination of conditions related to the Puerto Rican experience and the educational expectations internalized by different national origin groups. For example, evidence on the residential patterns of Puerto Ricans suggests substantial segregation in the U.S. (Massey & Denton 1993). That is, similar to the experiences of African Americans in the U.S., many U.S.-born Puerto Ricans reside in places with little economic opportunity. Under such circumstances, the perceived value of a high school or college degree may be less than in other more economically successful neighborhoods, with the result that more youths drop out of school without receiving a diploma. Therefore, to develop a better understanding about the lower

achievement of U.S.-born Puerto Ricans, future models of educational inequality should consider the impact of residential segregation and neighborhood opportunities on educational attainment.

As we suggested earlier, the higher achievement of U.S.-born children of foreign-born Mexican parents may result in part from the perceptions of immigrant parents about opportunities for their children (Ogbu 1987; Rong & Grant 1992). Foreign-born parents may have higher expectations than U.S.-born parents, or they may guide their children in more ways that help promote educational attainment than U.S.-born parents. For example, school-related practices, such as parental encouragement and attention, monitoring of schoolwork, supervision of activities, and expectations, are associated with higher school achievement (Astone & McLanahan 1991). It may be that Mexican-born parents who bear children in the U.S. spend more time engaging in these practices than other parents of Mexican children.

Thus, future research of race and ethnic differences in educational achievement must emphasize both the importance of family processes and cultural perceptions of barriers to achievement. Addressing these issues requires data that measure macrolevel attributes such as neighborhood characteristics and microlevel factors such as parenting practices. We believe these may be the missing elements needed for a comprehensive explanation of the educational attainment of Mexicans and Puerto Ricans.

Notes

1. Assimilation theory predicts that the least assimilated, the foreign born, will have lower educational attainment than the partially assimilated, the U.S.-born of foreign-born parents, who in turn would have lower educational attainment than the native born of U.S.-born parents.
2. We refer to island-born Puerto Ricans as "foreign born."

Economic Decline, Gender, and Labor Flexibility in Family-Based Enterprises: Midwestern Farming in the 1980s

LINDA LOBAO, *Ohio State University*
KATHERINE MEYER, *Ohio State University*

Abstract

During economic downturns, traditional gender allocations of labor have been considered to vary more than in prosperous times. While most studies have examined the division of labor in the household or in paid employment, we examined it where both intersect, in family-owned and family-operated enterprises in the farm sector of the 1980s. This context, combining crisis conditions and the agency of economic actors, should be related to greater flexibility in labor allocations, leading to the feminization of farming. However, a contrasting perspective argues for rigidity of gender roles in farming. We use data from a twelve-state midwestern sample and a more detailed Ohio study. The results failed to support the flexibility thesis. The rigidity of production roles was further translated into different factors related to women's and men's stress.

Gender divisions of labor usually are considered most malleable during periods of economic decline (Hareven 1990; Lipman-Blumen 1984). In such times, survival necessitates rationalistic allocation of labor resources, presenting openings for women to broaden participation in work and occupations formerly reserved for men. Most research on the division of labor in the contemporary U.S. focuses on separate spheres of paid employment in the formal sector and household reproductive activities. This study examines work roles where household and enterprise intersect, in family-owned and family-operated businesses. We focus on an economic sector that experienced a dramatic downturn in the 1980s — midwestern farming — and examine gendered

patterns of work in the farm enterprise, household, and paid employment during the farm crisis. In particular, we question whether a traditionally male-dominated industry became more feminized and document the implications of gendered work patterns for emotional well-being.

Several literatures address the gender allocation of labor in times of hardship and economic decline. Historical work examines women's employment during war and depression (Elder & Liker 1982; Hareven 1990). Studies of Third World women document their use of work-related survival strategies, including informal sector employment, to cope with economic hardship from national structural adjustment (Daines & Seddon 1993; Moser 1992). Research on contemporary Western societies describes how gendered patterns of paid employment vary by industrial sector during recessionary periods (Bagguley et al. 1990; Cummings 1987). These literatures view macrolevel changes as the structural context of a historical period. Change washes over economic actors differentially, depending upon prior social statuses. Women's domestic responsibilities are argued to remain constant despite added productive work outside the household. As a consequence, some analysts contend that women bear the costs of economic crises, in terms of multiple work burdens and higher stress relative to men. The farm sector during the 1980s provides a useful context for elaborating these employment and personal outcomes.

Most knowledge about contemporary economic structure is from research on paid employment, large firms, and urban settings. Less is known about family enterprises that have (1) no clear separation between labor and capital, (2) depend mainly on unwaged labor, (3) integrate spheres of production and consumption, and (4) share other informal sector attributes (Aronson 1991). The survival of such enterprises in advanced economies are of increased sociological concern (Castells & Portes 1989; Collins 1990; Mingione 1991). The ability to mobilize unpaid household labor, particularly that of women, results in a more flexible work force, enhances competitiveness, and enables small-business owners to resist taking salaried employment. The advantages of household labor have been well-documented in the case of farming and explain why family businesses dominate numerically in that sector (Friedmann 1978). Highly fluctuating market conditions have characterized farming historically. During downturns, households are able to sacrifice economically by increasing farm and off-farm work and by reducing consumption levels. While such strategies involve all family members, women have been seen as particularly stressed and triply burdened with household work, farm work, and nonfarm income-generating activities.

Farming is also an industry where the division of labor historically has revolved around gender (Rosenfeld 1985). It provides an opportunity to examine whether traditional divisions of labor relaxed during crisis. More broadly, as family-based production, farming enables the exploration of how producers themselves, in settings less constrained by capitalist managerial imperatives, act to preserve or eliminate gender-segregated activities. Farming during the 1980s thus offers a context in which crisis conditions and the flexibility of economic actors should alter traditional work roles. Our focus is to examine employment and personal outcomes in this context of general economic decline and through the farm household variations within.

Context of Farming in the 1980s: The Historical Period and Farm-household Differentiation

The 1980s represents the worst financial stress in the farm industry since the Depression (Lasley et al. 1995; Murdock & Leistritz 1988; Stam et al. 1991). Some analysts view the crisis as a fundamental breakdown in the regulatory structure of farming under Fordism, particularly due to changes in globalized agricultural commodity markets (Kenney et al. 1989). While other interpretations have been posited, most scholarly work recognizes that the crisis was the result of both long-term structural trends and specific economic events. Historically, U.S. agriculture suffered from problems of overproduction, unstable and low farm incomes, and high government support costs. Exportation of agricultural commodities was encouraged in the late 1960s as a strategy for managing these problems. In the process, farming became more vulnerable to new sources of price and income instability (de Janvry & LeVeen 1986). Over the 1970s, farm exports expanded almost sixfold. Farm prices rose, and farmers expanded operations by investing in land, machinery, and equipment. Often they borrowed heavily to do so (Leistritz & Murdock 1988).

The conditions fostering the agricultural boom of the 1970s reversed in the early 1980s. Farmers were faced with a national recession and a decrease in world demand for U.S. products due to the rising value of the dollar, the Soviet grain embargo, and increased market competition from other producer nations. Interest rates and the costs of producing farm commodities continued to rise and commodity prices fell. As returns to farmland diminished, land values declined: they fell 27% nationally from their 1981 peak to almost 60% in 1986 in export-sensitive midwestern states (Leistritz & Murdock 1988). Real median real estate value plunged from $351,157 per farm in 1982 to $270,471 in 1987, its lowest rate of the crisis (Jones & Canning 1993). Declining land and other asset values eroded farmers' equity and, coupled with lower farm income, made servicing debt difficult. By 1986, about one-fifth of all farmers were considered to be in financial stress. Forced sales of farmland jumped from 19% of all farmland transfers in 1980 to 46% in 1986. The percentage of farms going out of business tripled and the percentage going out through bankruptcy more than quadrupled from 1982 to 1986. By 1990, from 8% to 12% (200,000-300,000) of those farming in 1980 failed financially, becoming bankrupt, foreclosed, or financially restructured (Stam et al. 1991:2).

We should note that analysts refer to the farm crisis as beginning in the early 1980s rather than linking it to any one year or specific event. Signs of crisis are documented retrospectively, with the years 1981-83 representing clear shifts toward rising real interest rates, declines in land values, and plummeting farm exports. However, the severity of these changes for the sector's financial well-being was not recognized by the federal government or academia until about 1984, mainly because of the lack of current information about farm debt distribution, bankruptcy, and other financial conditions (Harl 1990; Stam et al. 1991). The media introduced the farm crisis to the public mid-decade (Harl 1990).

While the farm crisis represented an industry-wide decline, specific enterprises were affected differentially, as in any sectoral downturn. The crisis

varied across regions, enterprise size, and commodity specialization. Midwestern farms were hard hit due to their cash grain specialization. Commercial farms defaulting on loans were concentrated in this region (Hanson 1990). Financial stress affected particularly middle- to upper-middle-size commercial units (about $100,000-$250,000 in gross annual sales) that are less able to manage high debt loads. Younger farmers were affected because they were newer, more highly leveraged entrants into farming. In the case of family enterprises, declines tend to be directly reflected in household well-being. Economists have long recognized the fungibility of financial assets in family enterprises (Aronson 1991), and sociologists have stressed parallel linkages of production and consumption (Mingione 1991). During the crisis, farm households were observed to cutback on consumption expenditures in accordance with enterprise conditions (Barlett 1993; Belyea & Lobao 1990; Johnson, Lasley & Kettner 1991). The household conditions of the farm population thus varied during the crisis period.

A characterization of the 1980s farm economy must consider not only the financial crisis but also previous rounds of restructuring that differentiated enterprises and households. Paralleling the development of other industries in postwar Fordism, farming grew more capital-intensive and concentrated, an increasingly specialized mass producer of food. This system, which emerged in part from New Deal policies to alleviate the Depression in farming, performed quite well until the crisis period, albeit with enormous consequences for farmers and rural people. From 1940 to 1990, the number of farms declined by two-thirds and the farm population shrank from nearly a quarter of all Americans to about 2%. Most of this massive restructuring had occurred by the 1970s. A dualistic farm system now exists marked by a relatively large number of small, part-time farms and a few large farms with expanding market-shares. Moderate-size family farms, those closest to the petty bourgeois ideal in which household members own the major production factors, use minimal hired labor and depend mainly upon farming for livelihood are being edged out of this system (Krause 1987; Lobao 1990). Concomitantly, the class structure of the farm population has become increasingly internally stratified (Mooney 1988). Producers occupy a range of class positions on both sides of the petty bourgeoisie, from semi-proletarianized to capitalist or hired-labor-dependent farmers. In summary, the 1980's farm crisis was an industry-wide, cyclical downturn that occurred in a system in which enterprises varied in size, in asset holdings, and in general production-related characteristics. Households varied by consumption conditions and class location as well.

Gender Allocations of Labor in a Context of Decline: Flexibility vs. Rigidity

Two contrasting perspectives on the broadening of work in direct production can be delineated. Both assume that in family enterprises, production and consumption and farm and household well-being are linked. Both see individuals' labor allocations as a function of production and household characteristics, but they differ in including gender as a guide in this process. Both literatures treat relationships as period and position effects. That is, they view women's

and men's labor allocations as adaptations to a particular economic environment. Labor allocations vary among family enterprises to the degree that they are marginalized in this environment.[1]

FLEXIBLE LABOR ALLOCATIONS: OFF-FARM WORK AND THE FEMINIZATION OF FARMING

The first perspective suggests that both women's and men's participation in production should be more flexible in periods of downturn. Enterprise stress confers shared household conditions and experiences. Farm men and women should adapt by intensifying or expanding production and/or increasing off-farm employment. Relative to the past, farm women are likely to have greater involvement in farming and off-farm employment in the 1980s. Several literatures support this expectation of work role broadening.

Neoclassical economic theory, as articulated in the new home economics, assumes that households are decision-making units. Household welfare is dependent upon rational allocation of labor and consumption resources and on adaptation to economic environment (Becker 1981; Pollak & Wachter 1975). In order to maximize welfare, households should allocate members' home and market work time by criteria such as human capital skills, external labor market characteristics, and substitutability of purchased home inputs for member-provided ones. While the new home economics has been criticized by sociologists on a variety of fronts (England & Kilbourne 1990; Spitze 1986), it has served to bring household dynamics into the analysis of the farm enterprise (Huffman 1991). Nearly all research on farm household labor by economists or home economists is framed in terms of neoclassical assumptions. Most studies focus on the operator's and, less frequently, on spouse's off-farm employment and were conducted prior to the farm crisis. Virtually all research is cross-sectional. From this perspective, households allocate men and women to farming or nonfarm employment based upon household, farm enterprise, and local labor market exigencies (Findeis, Lass & Hallberg 1991). Gender segregation in farming activities due to ideology, tastes for tradition, or patriarchal control is little addressed but would be seen as nonrational and diminishing in times of crisis.[2]

Political economy perspectives also have emphasized the flexibility of family labor in periods of hardship and change (Walby & Bagguley 1989). While conflicting with neoclassical economic perspectives about why family enterprises survive under late capitalism, this literature often makes similar assumptions about household consensus and the rationality of survival strategies. Maintaining the enterprises' economic position, particularly so that wealth can be passed down to subsequent generations, tends to be viewed as equally important for all household members. In effect, class-based group interests are seen to override potential gender interests in allocating household labor. As noted above, historical evidence shows that women's labor in farming and in nonfarm employment has been mobilized during economic downturns, enabling family farmers to survive and compete with larger-scale units (Friedmann 1978; Stock 1992). However, the extent to which this has occurred in recent years is unclear.

While there is little quantitative information on shifts in women's farm work during the 1980's farm crisis, researchers have extrapolated from case

studies and earlier work to contend that farming became more feminized. Gladwin (1991) argues that role flexibility likely increased during the crisis. Her north Florida study found that women reported spending more time at farming and were a labor substitute for their spouses who were working off-farm to maintain family income. Such substitution occurred in part because rural men have higher wages than women. Friedland (1991) notes that general restructuring of farming in the 1980s, particularly the relative increase of part-time farming on small farms, did feminize farm work. Other work that does not specifically address the U.S. crisis supports these contentions. Some studies that focus on the structural position of the enterprise have found that women participate more in production on smaller, less-profitable units (Buttel & Gillespie 1984; Coughenour & Swanson 1983); and conversely, that gender segregation in farm work and marginalization of women from decision making is greater on higher-volume commercialized units (Sachs 1983). Studies of other first world countries also suggest that production is feminized when units are a less viable means of household support (Pfeffer 1989).

Finally, literature on occupational segregation, although centered on paid, formal sector employment, may offer insights about labor allocation in family enterprises. Arguments that women constitute a "reserve army of labor" when the supply of male labor is low (Jones & Rosenfeld 1989) support previous contentions that women perform farm labor for spouses who work off-farm or to reduce the costs of hired help. Furthermore, employment demand for men may be higher because rural labor markets are often composed of extractive industries and because the midwestern markets are composed of durable manufacturing. Research indicating women's greater representation in sectors that have been deskilled and poorly remunerated (Tickamyer & Bokemeier 1988; Walby & Bagguley 1989) also suggests that women's presence in farming should be greater during downturns.

RIGIDITY IN FARM LABOR ALLOCATIONS

A contrasting perspective is from feminist and other literature that focus on statuses within the family. Although this literature suggests that both men and women allocate labor flexibly outside the family enterprise, the reasoning for this is grounded in gender-based rather than collective household interests and experiences. Moreover, it indicates that the division of labor on the enterprise itself will be little altered in contexts of decline. Edwards (1979) characterizes small enterprises by their use of coordination or control systems. In the former, work is organized by consensus, through workers' recognition of mutual production goals, shared control or ownership over factors of production, and equitable remuneration of work. In small enterprises using simple control, positions in production take a more hierarchical form, with a designated person or persons directing, evaluating, rewarding, and disciplining the work of relatives and hired labor. Literature that centers on collective household interests in the allocation of labor by family businesses implicitly assumes the use of coordination over control. In farming, as in other family businesses, both processes operate to varying degrees. Methods of controlling and structuring the

labor force penetrate family farming in the guise of kinship relations of gender and generation (Wilson, Simpson & Landerman 1994).

Recent feminist work has documented the intransigence of asymmetrical family relationships in farming. Most women confront farming through their positions as wives, in structurally subordinate positions in the family enterprise (Whatmore 1991). This position confers specific roles and responsibilities, subject to human agency, in farm production and household reproduction. Women are situated in a "patriarchal labor process" in which the timing, nature, and outcomes of their farm work tend to be directed by men and coordinated around household exigencies. While the gender division of farm labor varies by enterprise characteristics, commodity, family norms, ethnicity, and other factors, the general trend is that men retain greater control over operating decisions such as marketing, input purchases, and major production tasks such as field work (Barlett 1993; Rosenfeld 1985; Salamon 1992). Men's control is reinforced by their greater property ownership and by institutions such as the Agricultural Extension Service, agricultural cooperatives, and farm organizations with a legacy of serving men's production needs foremost (Sachs 1983). As a consequence, men stand at the apex of the operation and women in more distant roles (Simpson, Wilson & Young 1988). Thus, the distinct statuses of men and women in the family enterprise suggest that women should experience and respond to downturns in different ways from men. From this perspective, traditional divisions of labor are likely to remain fixed in crisis.

Evidence supporting rigidity in farm work is from studies finding that men's and women's labor allocations do not revolve similarly around enterprise exigencies, which distinctly influence men's farm and off-farm labor but tend to have little effect on women's (Simpson, Wilson & Young 1988). The greater the commercialization or scale of the farm and the more hired labor use, the more time men allocate to farm work and the more they reduce off-farm work, relationships that do not hold for women. In contrast to studies above that find farm work more feminized on smaller, less-profitable units, other work points to a continued lack of women's substitution for men and hired labor (Whatmore 1991; Wilson, Simpson & Landerman 1994). Enterprise commercialization is shown to be little related to women's work in both farming and nonfarm employment (Simpson, Wilson & Young 1988) or to affect women's farm work only in certain ethnic and community contexts (Salamon 1992; Shaver & Reimer 1991). These gender differences are reflected in the determinants of farm and off-farm work, age, education, and other demographic characteristics for both women and men and enterprise characteristics for men (Lyson 1985).

In sum, this perspective emphasizes that women are situated in the farm-household production nexus in different ways from men. The experiences and interests associated with this position should structure their response to crisis differentially as well. Because women historically have had blocked opportunity in farm management, their likely response to perceived hardship and change is to look first to the nonfarm economy. Hence, women's labor allocations are thus likely to remain rigid in the farm enterprise but elastic with regard to off-farm work.

Production, Household Reproduction, and Stress: The Gendered Costs of Labor Allocations

Focusing on labor allocations in the crisis period allows us to elaborate upon a frequently echoed theme, that the costs of economic crises are gendered, with women often experiencing greater hardship than men in terms of increased work burdens and personal stress (Daines & Seddon 1993; Elder & Liker 1982). Women's stress in hardship contexts has been attributed to their continued responsibility for household reproduction despite increased work outside the household and to women's greater sensitivity to declines in consumption levels, resulting from their roles as household and community managers (Coverman 1989; Hochschild 1989; Tilly 1981). Farm women's stress was recognized as a national social problem at the turn of the century, as the Roosevelt administration feared that women's extensive work burdens would spur farm families toward rural out-migration and, in turn, escalate food costs (Sachs 1983). Some studies report that contemporary farm women have significantly higher levels of social-psychological stress than men (Meyer & Lobao 1994; Walker & Walker 1988; Duncan, Volk & Lewis 1988), attributing this to the multiple roles these women play and to their day-to-day management of household consumption. More detailed case studies of farmers during the crisis link social-psychological stress to household economic position and labor allocations in different ways for men and women (Barlett 1993; Conger & Elder 1994; Rosenblatt 1990). For men, stress is more connected to their occupational status as farmers while for women it is more connected to family lifestyle. We extend our analysis to women's and men's stress to assess the extra-economic costs of pursuing gendered strategies of labor allocations and to examine the implications for farm peoples's ability to underwrite the present agricultural system.[3]

Research Questions

Although a number of studies examine farm women's and men's farm- and off-employment, few consider the 1980's crisis. Of those existing, nearly all focus on off-farm employment. Farm women, relative to farm men, to other rural women, and to the past, appear to have increased their participation in the labor force in the 1980s (Ollenburger, Grana & Moore 1989). McDonald and Peters (1991) examined the labor force participation of farm women and men in seven West North Central states using data from the *Current Population Survey*. In 1989, 58% of farm women 16 and older were in the labor force as compared to 45% in 1979. A number of questions remain about farm household labor allocations during the crisis period. First, the extent to which farm enterprise and household conditions influenced off-farm labor allocations is unclear. Studies using secondary data, such as those above in which farmers are a subset of the general population, are limited because they lack detailed enterprise data such as debt levels, enterprise capitalization, commodity specialization, and household indicators of financial stress. As a consequence, researchers have inferred rather than directly demonstrated that women's off-farm participation increased due to the hardships of the crisis. Second, as noted above, there is

little information about whether the traditional division of labor in the enterprise itself was altered. Third, the household division of labor is generally unexplored. Although studies of other populations indicate that women's domestic responsibilities remain unchanged, some case-study accounts suggest that men increased domestic tasks as wives took on greater roles in farm or off-farm production (Davidson 1990).

We analyze these questions by considering the farm crisis in two ways, as a structural or macrolevel context and through the gradations of household-enterprise economic positions within this context. As noted earlier, analysts have typically analyzed decline in terms of temporal setting and/or through differential positions that manifest decline. Based upon the previous literature, we expect that in the 1980s, expansion of work domains to the nonfarm sector is likely for both men and women. Total time spent in productive work may also increase. Men may intensify their on-farm work, particularly those with larger operations. Perspectives about women's farm work lead to contrasting hypotheses: one indicates a greater feminization of production, the other indicates little change in women's farm activities and even possible decrease as women exit farming for off-farm employment. Within this context, differential household enterprise characteristics should shape labor allocations. In family businesses, production and consumption are intermixed so that labor allocations of both men and women should be related to enterprise and household financial stress. However, the two perspectives differ as to how gender guides labor allocations and its outcomes. One implies increasing similarity between men and women in interests and experiences of crisis and substitutability of women's for men's labor. The other argues that because women occupy differential structural positions in the family enterprise, their interests and experiences likely vary from men's, their labor allocations stand to be affected by different factors, and they likely will not substitute for men working off-farm or on marginal units. Finally, we pose questions about outcomes beyond the allocation of work in production. Did men increase their share of domestic duties? To what extent did changes in work patterns and related crisis experiences result in differential patterns of stress for women and men?

Data and Methods

This study is based on data from two sources. Considering the crisis period as a structural context within which farm people acted, we present a broad description of the patterns and reported changes in women's and men's work activities for twelve midwestern states. We used a more detailed Ohio sample to examine the gradations of household-enterprise economic conditions within this context and the extent to which these were related to women's and men's labor allocations.

THE MIDWEST STUDY

The midwest is composed of the Lake states (Minnesota, Michigan, and Wisconsin), the Corn Belt (Ohio, Illinois, Indiana, Iowa, and Missouri), and the Plains states (North Dakota, South Dakota, Kansas, and Nebraska). In 1988, about one-fifth of Midwest farmers had debt-to-asset ratios (a commonly used measure of financial stress) over the standard 40%, indicating serious-to-extreme financial difficulty. This proportion of operators was nearly double that of the south and southeast and higher than all other regions (Morehart, Johnson & Banker 1988). Between 1980 and 1990, 64% of all counties in the region lost population, a reflection of the farm crisis and downturns in other rural industries.

In 1989, data were collected from a random sample of farm households within each of the twelve states. Two questionnaires were sent — one for the "person responsible for the majority of farm operation decisions" and one for his/her spouse or household partner. Single farmers were asked to complete only one survey, which focused mainly on production needs and techniques and farm-household finances. The partner survey focused on changes in the division of labor and personal involvement in farming as a result of the crisis, perceptions about adjustments, and life stressors. A total of 4,087 individuals completed the production survey, and their 3,630 respective spouses or household partners completed the partner survey.[4] About 98% of those completing the partner questionnaire were women and 97.3% of those completing the production survey were men. About one-quarter of the farms had debt-to-asset ratios exceeding 40%. About 42% of the sample had net family incomes of $20,000 and below.

THE OHIO STUDY

The Ohio study provides more detailed comparisons of men and women. The Ohio study is part of a longitudinal project monitoring approximately 900 farms selected randomly from a list of all Ohio farms (approximately 70,000) that were provided by the Ohio Agricultural Statistical Service. Telephone interviews collecting basic farm production and household demographic information were conducted in 1988. A detailed financial balance sheet was created for income and expenses for the previous year, 1987. Separate mail-out questionnaires focusing on the division of farm and household labor (including the major variables used in this study) were then sent to each operator and spouse/household partner. This analysis uses data from the 531 men and 497 women who completed the mail-out survey and whose farms were included in the telephone interview. About 98% of the women and 90% of the men are married and the sample was composed of 86% matched couples. Farm characteristics typify the Corn Belt pattern of smaller commercial family farms. Most farmland is owned by the household, and enterprises use little hired labor. The pattern of smaller farms results in a less highly leveraged population than in the Plains or Lake states of the midwest. The Ohio sample was similar to the rest of the Cornbelt in that about 17% of farmers had debt-to-asset ratios exceeding 40%, above the national average. Median family income in 1987 was $26,331 for the sample, about $4,500 below that for the nation for the same year

(U.S. Bureau of the Census 1991). About the same proportion (43%) as in the midwest farm survey had family incomes lower than $20,000.

The Gender Division of Labor and Work Patterns during the Crisis Period

WOMEN'S AND MEN'S INVOLVEMENT IN ENTERPRISE, HOUSEHOLD, AND OFF-FARM WORK

Women were asked to report how often they perform a variety of tasks that take place on their farm following Rosenfeld's (1985) delineation, and whether they do these regularly, occasionally, or never. These data are shown for women completing the partner survey for the midwest ($N = 3{,}391$) and for both men and women in Ohio (Table 1). Although there are three farm production subregions within the midwest, there is little regional variation among them in any of the following analysis, making it more parsimonious to report regional totals. Women's involvement in direct farm production is similar to that reported in earlier studies. Most perform farm tasks at least occasionally but are at a greater distance from management responsibilities (Rosenfeld 1985; Simpson et al. 1988). Although women did bookkeeping on a regular basis, they were far less likely to do field work and to participate in management tasks such as marketing, purchasing inputs, and supervising labor. The Ohio data revealed gender differences more distinctly, as data on division of labor were collected for both men and women. More than half the women contributed at least occasionally to harvesting crops, raising farm animals, running errands, and keeping a home garden. At the same time, they were nearly wholly responsible for household tasks.

The frequency of off-farm employment across the midwest and in Ohio is reported in Table 2. Off-farm employment refers to whether or not the respondent worked at either a paid job outside the home or farm and/or was self-employed (in addition to farming).[5] Women were more likely to be employed off-farm than men. Respondents were also asked whether or not they took off-farm employment "because of financial need in the past five years." Since the widespread realization of the crisis circa 1984, 38% of women took off-farm jobs compared to 23% of men. Thus, farm people reported further semi-proletarianization and at rates that varied by gender. As would be expected from the postwar differentiation of the farm sector, however, most people working off-farm did so prior to the crisis with men having worked a median of 16 years and women, 9 years. About two-thirds of midwestern farm women and three-quarters of men worked off-farm 30 hours or more per week during the crisis (Table 2). Women seemed to occupy jobs created during different epochs of rural economic restructuring. About one-third were in traditional women's rural professional jobs, such as teaching and nursing. Historically, education and hospitals and health services have been large employers in rural areas. Nearly half of the women occupied lower-wage jobs in the more recently expanding service sector. The more detailed Ohio sample shows that about 20% of employed women were self-employed and engaged in informal sector activities such as baby-sitting, house cleaning, and providing business services. About one-third of midwestern net family income came from women's

employment, slightly higher than the proportion contributed by working wives nationally (Ritchie & Pollard 1994).

CHANGES IN LABOR ALLOCATIONS DURING THE CRISIS PERIOD

Midwest women were asked to report changes in work roles in the past five years or since about 1984 (Table 3). Most reported that the time they spent at various farm and household tasks stayed the same. For those reporting changes, declines exceeded increases for all categories of farm work except bookkeeping. The Ohio sample showed specific gender differences. A greater proportion of men increased rather than decreased time spent in caring for farm animals, marketing, and bookkeeping. Men's reported decreases were in supervising labor and in field work but those changes were lower than those of women. These differences are reflected in changes in general farm involvement, with a higher proportion of men reporting increased relative to decreased involvement in farming and women reporting the opposite.

The amount of time spent at an off-farm job increased for 20% and decreased for 16% of the women. In Ohio, 28% of women reported increases as compared to 17% of men and only 8% of both men and women reported decreased off-farm work. In Ohio, off-farm employment appears to have accelerated during the crisis period, possibly due to the greater availability of nonfarm jobs and to the smaller size of farm operations. In contrast to case-study observations, men did not increase their share of domestic work relative to the past or to women. While changes in work involvement in farming and nonfarm employment may have reflected the effects of aging, eliminating farmers older than 70 showed the same gender gap and relatively little change in the percentages reported in

TABLE 3: Changes in the Amount of Time Spent on Farm, Household, and Off-Farm Work since 1984

Table 3. In sum, there was little evidence that farming became feminized during the crisis period. Rather, for women who changed work roles, the most likely path was to become more distant from farming, relative to men, by expanding off-farm employment.

Household-enterprise Position during the Crisis: Gendered Labor Allocations and Stress

The Ohio study provided a more detailed, empirical test of the factors affecting the gender allocation of labor in paid work and in farming. We hypothesized that the financial position of the household-enterprise during the crisis is related to the labor allocations of farm people.[6] Further, due to men's and women's respective structural positions in the farm household, we expected that different factors influenced their labor allocations. Women also should be more sensitive to economic restructuring, as it is manifested through household financial hardships, and possibly experience greater social-psychological stress.

MEASURES

All variables are described below. Means and significant differences between men and women based on *t* tests are shown in Table 4. We employed five measures of work involvement. Whether or not the respondent participated in *off-farm work* and *off-farm work hours,* were described previously. For the Ohio sample, off-farm work and off-farm hours specifically included time spent in nonfarm informal sector activities, such as home-based production and personal services. We reported off-farm work hours only for those who had off-farm work. Time spent at *farm work* was calculated from the average number of hours spent weekly for each season on farm work (however the respondent defined

this). Respondents indicated their work time on a five point scale of hourly intervals for all four seasons. The midpoint of each hourly interval was taken and then divided by 4. Men reported spending about 36 hours per week annually in farming and women, about 12. *Changes in off-farm and farm work time* referred to the last two items in Table 3, whether this work increased (3), stayed the same (2), or decreased (1) since the crisis.

We delineated independent variables that reflect structural attributes of the enterprise, enterprise-household conditions, and control variables for personal/sociodemographic characteristics and labor market context that are commonly used and central to the two perspectives above on farmers' labor allocations.

Farm Enterprise Structure

Enterprises varied as to their structural position in the farm industry at the time of the crisis. We used several measures of farm structure that have been commonly associated with labor allocations. Extent of farm commercialization is measured in terms of size and hired labor use. Farm size is measured through a commonly used measure, *gross sales* from farming. Farms were placed into one of seven standard size classes ranging from (1) under $10,000 to (7) $500,000 and over, with median sales about $40,000. Because most farms used little hired labor (with total median annual usage about 80 hours), we created a dichotomous variable, coded 0 for no hired labor and 1 for use of hired labor. The commodity produced affects the amount of time that must be spent on farm work and is linked to prices received during the crisis. Farms were classified by two types of commodities, cash grains and dairying. Cash grain operations require less continuous labor. Cash grains also experienced their lowest prices of the 1980s in 1986-87. Dairy operations are controlled because they require continuous labor, constraining off-farm employment. *Cash grain dependency* is measured by the proportion of gross farm income from sales of cash grain and inventory value. Farm operations are coded 1 if mainly *dairying,* 0 if not. Table 4 shows no significant differences between men and women on the farm enterprise variables as would be expected since most of the sample are matched couples.

Farm-Household Financial Conditions

The financial position of household and enterprise are intertwined in family enterprises. We used both objective and subjective or perceptual indicators of financial conditions to indicate varying positions among farm households during the crisis. The *debt-to-asset ratio* is an indicator of financial stress, reflecting solvency and operating risks.[7] It is measured by the ratio of total farm and household liabilities to total assets for the year prior the study (1987). Financial hardship should be evident through behavioral adjustments in household consumption. To measure adjustments in consumption expenditures, we used an index developed by Bultena, Lasley and Geller (1986). It was created from affirmative-negative responses to 13 adaptations made by the family in the past year to financial stress such as: postponing major farm purchases; postponing major household purchases; changing food or eating patterns to save money; purchasing more on credit; and postponing medical

care to save money. A simple additive index of "yes" responses was tallied, then divided by the total number of items to calculate an overall score. Cronbach's alpha coefficient for the internal consistency of this measure, *financial adjustments,* is .825. The mean adjustment score for women is .34, indicating that on average, women report that their families made about 34% of the adjustments. We used two indicators of subjective perceptions of financial conditions. *Perceived economic hardship* was measured by a three-item scale from Pearlin et al. (1981), questioning respondents how often in the past year their households could not afford adequate food, clothing, or medical care. Frequent problems in affording household medical care were reported by 11% of women and about 20% reported frequent difficulty in affording needed clothes. Higher scores on the index indicate greater hardship. *Dissatisfaction with finances and quality of life* was composed of five items rating satisfaction with farm family financial and social well-being at present, relative to the past, and for future potentials. Higher scores indicate higher dissatisfaction. Cronbach's alpha coefficients were above .75 for each of the two indicators of subjective perceptions. As we expected from women's roles in mediating family consumption needs, women were significantly more sensitive to deterioration in household conditions than men, reporting greater consumption cutbacks, hardships, and poorer enterprise-household finances (Table 4). We also included family income because it is often used as an independent control variable in models predicting off- and on-farm work and work hours (Buttel and Gillespie 1984; Simpson et al. 1988). Farmers with higher family income were more likely to work off-farm. Net family income refers to annual income from the past year. It was coded into 10 categories to approximate an interval scale.

Sociodemographic Characteristics.

We included other household and personal attributes commonly used in studies of farm and off-farm work that are also germane to the two perspectives on the flexibility and rigidity of women's roles. Human capital characteristics of age, education, and farming experience should influence which household member allocates time to farm or nonfarm employment (Tickamyer and Bokemeier 1988). Age is also important because farmers in their younger stages of farming careers were more adversely affected by the crisis. Level of education was measured by a seven-point scale ranging from none (1) to graduate school (7); over half the sample completed high school (4). Farm background referred to main residence until age 16, (1 nonfarm, 2 farm) and reflected experience with farming as an occupation. About 89% of men and 55% of women had farming backgrounds. Because feminists emphasize property ownership as influencing women's participation in farming (Sachs 1983; Whatmore 1990), we use a scale measuring extent of ownership of capital assets, such as machinery and equipment, which ranged from (1) respondent holds title to none to (4) respondent holds title to all capital assets used on the farm. About 60% of men but only 26% of women had title to all capital assets. A similar scale of land ownership was not used as it had little variation for either men or women. Other control variables were: the presence of a spouse who works off-farm, which increases personal likelihood of off-farm work; and the presence of young children (number of children

aged 6 and younger). No controls for race or ethnicity were included; as is characteristic of the Ohio farm population, nearly all of the sample are white.

Labor Market Context

Farmers' labor allocations may also be affected by geographic context. Proximity to metropolitan areas is often controlled in models of off-farm employment but may not have much influence in Ohio as the state is relatively urban. Metropolitan proximity is a three-point index coded by whether the farm household is situated in (1) a nonmetropolitan county, (2) a nonmetropolitan, metropolitan adjacent county, (3) a metropolitan county. A more feminized nonfarm labor force, measured by the percent of the labor force that is female, may also be related to women's greater participation in off-farm work due to local labor demand. Both variables were measured prior to the crisis period, from the 1980 Census of Population.

Role Stress

Role stress was composed of five items with responses ranging from (1) none/no stress to (4) great feelings of stress. Items asked how frequently the respondent: is concerned with stress; experiences stress "on a day-to-day basis"; feels stress has increased over his/her farming career; has "problems in balancing work and family responsibilities"; experiences "pressure in having too much to do in too little time." The items were initially selected through a principal axis factor analysis for both men and women. Items that had high factor loadings for both men and women were retained and compose the index for which Cronbach's alpha is .82. Women reported somewhat greater stress levels than men.

STATISTICAL MODELS

The results reported in Tables 5-7 are from ordinary least squares regression analyses. Specification of the models followed that of previous studies of farm women's and men's work.[8] We also performed analyses adding other enterprise and spouses' characteristics, including work changes, but these did not alter the relationships presented.[9] Tests for the constancy of parameters (Hardy 1993) as well as the hypotheses to be examined, indicated the need for separate models for men and women.

WOMEN'S AND MEN'S ON-FARM WORK

Few characteristics of the enterprise itself influenced female participation in farm work (Table 5). As expected, women spent more time on dairy farms but other enterprise variables were not significant. The effects of crisis-related household conditions were evident in that women who reported greater financial adjustments or objective cutbacks in household consumption spent more time farming. However, perceptions about farm household conditions showed that women who were more dissatisfied with farm finances and life spent less time in farming ($\beta = -.159$), suggesting increased alienation. Prior farming experience and greater ownership of capital assets were related to greater farm work. Women who were older and those with younger children

reported less time in farming. Women also adjusted their time spent in farming relative to off-farm work, as indicated by the significant negative relationship between off-farm work hours and farm work. For men, larger farms increased time spent in farm work. Men on cash grain farms reported slightly less work time. In contrast to findings for women, greater dissatisfaction with farm household finances and lower family income were significantly related to greater time spent on farm work for men. This suggests a pattern commonly noted in case studies of the crisis period in which the full-time farmer experienced low income and frustration with farm life (Davidson 1990; Heffernan & Heffernan 1986). For women, age, nonfarm background, and greater hours spent in off-farm work reduced time spent farming. Labor market variables had little impact on farm work.

Changes in women's time spent farming over the crisis period were little affected by financial hardship or enterprise structure, supporting the second perspective on the inflexibility of women's farm work. Women who increased their off-farm work time concomitantly decreased farm work time rather than increased total work time in both domains. This conflicted with expectations derived from historical accounts of past crises in which farmers increased total labor time and self-exploitation. Women who owned more capital assets and came from farm backgrounds were no more likely to have increased farm work than other women. In contrast, men's farm work increased as a response to financial hardship and to rationalistic economic criteria. Men who perceived greater economic hardship, whose households operated larger units, and who personally owned greater capital assets were more likely to increase farm work.

In sum, these analyses supported the second perspective of gender rigidity in farm work. Women's labor allocations were only slightly responsive to enterprise exigencies and financial conditions despite a period of downturn. Because men tend to control farm operations, where possible (on large enterprises and for younger farmers), they responded with greater farm work during the crisis. Further, poorer financial conditions associated with the crisis context or feelings of economic hardship and dissatisfaction with finances were linked to greater farm work for men as well. Women remained more distant from farming and did not increase farm work time over the crisis period, even if they owned more assets and came from a farming background.

WOMEN'S AND MEN'S OFF-FARM WORK

Factors related to off-farm work similarly varied by gender with enterprise structure having little relationship to whether or not a women worked off-farm (Table 6). The major determinants of women's off-farm work were sociodemographic: higher education (β = . 240), younger age (β = -.275), the absence of young children (β = -.169), and having a spouse who works off-farm (β = .119). Women reporting greater household consumption adjustments were slightly more likely to work off-farm (β = .102) but this relationship was not quite significant. Coming from a higher income household and from a farm background also increased the propensity for off-farm work. Women who spent more time at farm work were less likely to work off-farm, indicating work domain trade-offs as found in the previous models. As expected, men's off-farm

employment was closely connected to the size of the farm enterprise ($\beta = -.401$). Farm-household financial conditions also influenced men's off-farm work. Men reporting greater household adjustments and higher debt were also more likely to work off-farm. As in the model for women, the presence of a spouse who works off-farm, higher income, and less time spent farming were related to men's off-farm employment. In contrast to women, however, farm background decreased men's off-farm work and education had no significant effect. Probit analyses were also run for this model. As the sample is relatively evenly distributed across the dichotomous dependent variable, the results are the same as for the ordinary least squares (OLS) analysis.

The analysis for time spent per week spent at off-farm work was performed for the 235 women and 200 men who reported off-farm employment. While fewer of the coefficients were significant in part due to smaller sample size, some general patterns were consistent with the previous model. Farm structure again had no significant effects for women, although there was a slight tendency for them to work more hours off-farm on cash grain and smaller units. Demographic variables were similar in direction for women as in the previous model. Women whose households made more objective financial adjustments in the past year worked somewhat longer hours ($p = .08$). Men's work time increased when they had smaller size farms, did not engaged in dairying ($p = .06$), and were slightly more dependent on cash grains. Higher family income and younger age were significantly related to greater hours spent in off-farm work for men. In contrast to findings for women, subjective perceptions of financial dissatisfaction rather than consumer adjustments were associated slightly with longer off-farm work hours for men.

Changes in off-farm work time were analyzed for the full sample. Support for contentions that farm women increased off-farm work due to crisis conditions was seen in the relationships for household-enterprise financial conditions. Women who perceived greater economic hardship and whose households bore higher debt loads reported increased off-farm work. As in previous models, younger age, higher education, and decreased farm work were related to increased time spent in off-farm work for women. Enterprise factors had no effect on women's off-farm work. Labor market variables also show significant relationships for understanding the spatial context within which farm women increased employment. Women more distant from metropolitan areas increased off-farm work, which corresponds to studies noting the greater integration of the most rural women into the labor force during the 1980s (Ollenburger et al. 1989). Women in counties with a more feminized nonfarm labor force also increased off-farm work. Taken together, these relationships suggest that farm women increased labor force participation more in those locales where such trends were set by nonfarm women. For men, changes in off-farm work were related to enterprise exigencies and demographic factors rather than to financial conditions. Men increased their participation in off-farm work on smaller, less commercialized units as indicated by the negative coefficient for hired labor. Younger men also reported increasing off-farm work.

FARM AND OFF-FARM WORK AND STRESS

To what extent did women's and men's work response during the crisis affect feelings of stress?[10] Women's labor force allocations and enterprise-household conditions were significantly associated with stress: increasing off-farm work, greater financial adjustments, and dissatisfaction with farm household finances and life (Table 7). Poorer household conditions during the crisis coupled with increasing paid employment thus created tension in women's lives. At the same time, paid employment increased women's independence from farming and farm men. Younger, better educated women, the population most at risk during the crisis, also had higher stress. Farm women from larger units and those with higher family incomes, perhaps reflecting the greater need to juggle duties on more affluent enterprises, had slightly higher stress levels. For men, factors related to the farm enterprise were most distinctly related to stress: increasing farm work rather than off-farm work, managing larger units, using more hired labor, and having lower dependency on cash grains, indicating continuous rather than seasonal production of commodities. As with women, financial cutbacks and dissatisfaction increased stress. Stress was also higher among men who reside closer to metropolitan areas, which may be due to the normative environment and complexity of farming near urbanized areas. In sum, this analysis showed that changes in labor allocations were concomitant with social costs, but not only for women as much literature contends.

Conclusions

A large literature has observed that U.S. businesses are responding to changes in the economic environment and conditions of competition by altering traditional divisions of labor and allocating labor more flexibly to production tasks (Piore & Sabel 1984). In contrast to most studies addressing this issue, we focused on family-owned and operated enterprises whose survival has hinged historically on a flexible work force. The 1980s farm sector provided a case in which financial downturn and the agency of household producers would be expected to alter traditional work patterns. We presented two alternative perspectives on women's and men's labor allocations in production during the crisis. One emphasized the allocation of labor based on enterprise features, human capital criteria, and similarities of men's and women's experiences during downturns. It suggested that both women and men should expand productive work with the result that farming may become more feminized. The other emphasized rigidity in family enterprise production and continued or increased marginalization of women in farming. Our findings showed that the way in which farm women and men allocated labor did not correspond to arguments about enterprise flexibility but occurred in a highly rigid way with little change in gendered work domains of farm or household. The consequences of patterns of labor allocations by gender were manifest social-psychologically, in a similarly rigid way.

We first presented an overview of labor allocations, considering the crisis as a context for change. Women tended to increase the amount of time spent in off-farm employment and to decrease the amount of time they spent in most

types of farm work relative to the past and to men. While most Midwest women and men who worked off-farm did so prior to the crisis, over one-third of women and about one-quarter of men reported taking employment due to financial need in the crisis period. In contrast to women's relative marginalization from farming, men were somewhat more likely to expand their farm work roles. Finally, men failed to broaden their scope of activities in household reproduction and despite women's off-farm employment, rarely did household tasks. In sum, there is evidence of gender rigidity and even divergence in farm work, stasis in household work, and convergence in becoming salaried employees.

Within the crisis context, household enterprises occupied varying positions relative to structural characteristics and financial conditions. We questioned to what extent household-enterprise factors are related to patterns of labor allocations. Here, too, factors impelling farm work and semiproletarianization were highly gendered. For women, poorer past enterprise-household conditions were linked to increased off-farm work, thus supporting some analysts' contentions that 1980s expansions in farm women's paid employment were partly crisis-related. For men, poorer enterprise-household conditions were more associated with increased farm work. In contrast to women, men worked longer hours when dissatisfied with farm household finances and life. As other studies found, farm structure had little effect on women's farm and off-farm employment, because men stand at the apex of direct production and management. For men, the size of the enterprise was a consistent determinant of their off-farm work. Men adjusted farm and nonfarm work according to the extent to which farm production could be expanded. For women, sociodemographic attributes were a consistent determinant of their off-farm employment: personal and household factors of higher education, fewer young children, and younger age. Women's farm work was related to sociodemographic attributes as well. However, there was no evidence that women expanded farm work in accordance with rationalistic household or personal factors outlined by perspectives arguing for flexibility in women's farm work. Women worked longer on the farm partly in the face of financial adjustments but also when they perceived improved household finances and quality of life. Women with farming experience failed to increase farm work hours during the crisis, indicating a rigidity of productive roles that belies human capital arguments.

The consequences of family enterprise restructuring also varied differentially by gender. We argued that due to women's position in the family enterprise, they would perceive greater enterprise-household hardship and decline than men, which was confirmed in the Ohio study. Women experienced slightly greater stress levels than men, compounded when their off-farm work, household's financial adjustments, and dissatisfaction with farm finances and life increased. Men's stress increased, in contrast, when time spent in farming rather than nonfarm work increased. Much of the literature on gender and social change has argued that women bear disproportionate costs of economic crises. By demonstrating that patterns of labor allocations, experiences of hardship, and relationship of these factors to stress varied between women and men, this study shows that women bear different rather than disproportionate costs of economic crises.

Despite the absence of wage labor in family based production, the farm sector provides an example where rapid decline has tended to leave the traditional enterprise division of labor intact. Gender differences in labor allocations are reflected even in patterns of stress: for men, increased farm work; for women, increased off-farm work. Why women's marginalization in farming persists is unclear from this study. Our data were limited to the Midwest, with little ethnic variation. The population, though in debt and with lower median income relative to the nation, generally owns most assets and few would be considered impoverished. In the past, women of color and poorer women have been more involved in direct production. Some researchers indicate that the institutional legacy of the agricultural system, government agencies and programs, farming organizations and cooperatives, and agribusiness firms, have been barriers to women's involvement, if not in the present, then certainly in the past (Rosenfeld 1985; Sachs 1983). Others have looked more to the dynamics of the family and to the extent of patriarchal control, values, and norms therein (Barlett 1993; Salamon 1992; Whatmore 1990). Women's labor allocations can also be seen as exiting from an organization of work that men have dominated historically. Women who work off-farm contribute to a fair proportion of household income, which in other contexts, has been shown to increase their power in the family. Had they increased farm work, instead, their labor time and output would have been more closely under the control of farm men.

Conceptually, the findings have implications for the linkage between human agency and social structure. Family enterprises, particularly in farming, have been viewed as holistic economic actors responding to economic change. Scholars have treated the "petit bourgeoisie" as "something like a 'family class'," whose independence and livelihood depends on the voluntary exploitation of family members and on the shared statuses that productive labor affords (Stock 1992:14). Women's unpaid labor is assumed to be highly elastic and readily available to compensate for labor needs and consumption shortfalls. The insight provided by our study is that prior social structural positions, as indicated by gender, are embedded within the family as an economic agent. The type of response to macroeconomic conditions is contingent on the gendered nature of positions. In brief, gender guides the ways in which macrolevel crises are experienced and ways in which responses are manifest.

The findings also have implications for the reflexive nature of agency and social structure. Not only does structure affect actors' lives but also their response alters this structure. Farm women's labor force allocations and household experiences have implications for the future trajectory of family-based production. The strategies that have enabled family farmers to survive and to compete with large, industrialized farms appear to be weakening. During the crisis, farm women and men did not increase both farm and off-farm work but traded time spent in one arena for that in the other. Farm work has been exchanged for nonfarm employment with women more likely to make this adjustment. Another typical strategy, reducing household consumption, is related to higher stress. The experiences of coping with fluctuating financial conditions and other aspects of farm production make social-psychological depression high among the farm population relative to nonfarm people and puts farming in the top ranks of high stress occupations. Off-farm employment

has long been viewed as a viable and relatively stable strategy that could maintain the enterprise in the face of economic downturns and support the farming lifestyle. Economic projections, however, are for the highest future losses in farming to come from smaller enterprises more dependent on off-farm income (Stanton & Olson 1990). Women's increased off-farm employment, somewhat higher stress, greater perceptions of financial hardship and farming dissatisfaction, suggest that farm women will be less likely to continue to underwrite the costs of direct food production relative to their male partners and past history.

Notes

1. The literatures reviewed in this section are framed in terms of both position and period effects. Analysts studying labor allocations by gender during periods of decline generally do not make explicit their conceptual strategy. Three analytic strategies can be seen. The most common strategy is to focus on a particular historical period and to assume that economic changes wash broadly over populations. Examples are studies on: labor allocations during the Depression (Elder & Liker 1982) and previous farming crises and downturns (Friedmann 1978; Stock 1992); women's employment survival strategies in Third World societies undergoing structural adjustment (Moser 1992); and work patterns during recession (Cummings 1987). With the exception of some historical work, these studies are based on cross-sectional samples and assume that the present economic environment is the structural context for studying the manifestations of macro-level changes. A second strategy (which some studies above utilize as well) is to focus on actors' positions which are assumed to result from economic decline, such as gradations of hardship and class variations. Cummings (1987) for example, examines women's labor allocations in industries assumed to have undergone different rates of restructuring, maintaining that the cross-sectional study provides a post-test of the effects of recession. Because nearly all studies on the farm crisis are cross-sectional, they assume that its effects are manifest over the industry at large during this period and also in the gradations of economic positions in which farm households are situated (e.g., the volume by Clay & Schwarzweller 1991). Finally, a third strategy used by a few ethnographic researchers centers on case studies of household labor allocations during the crisis (Barlett 1993; Salamon 1992).

2. Neoclassical economists suggest a number of ways by which economic downturn may be related to greater labor allocations of household members to productive work: objective declines in household income; objective differences between household income and the average income in the area of residence; perceived current income inadequacy or inadequacy relative to the past; and perceived income-consumption gap between one's household and reference group (Rubin & Riney 1994). Perceptions of income adequacy are further assumed to be shared among household members. In sum, although there is no single mechanism by which economic downturn is seen to affect household labor allocations, there is agreement over the end result of this process.

3. A summary of studies that examine stress during the farm crisis can be found in Wagenfeld et al. (1993). Most focus on farm-household economic position and stress and make similar assumptions as research on non-farm populations, that those in poorer positions during downturns have higher stress (Aneshensel 1992). The focus of this paper is not to specify the determinants of stress but to extend the literature on gendered divisions of labor by examining their extra-economic consequences.

4. The population list from which the North Central sample is drawn was provided by the state Agricultural Statistics Services. It is the most comprehensive list of farms available and covers the farms that are in the Census of Agriculture. In order to use the population list, we had to solicit independent cooperation from each of the 12 state Agricultural Statistics Service directors. Due to new confidentiality restrictions imposed by the Service, we were not allowed direct access to the list; we complied with the Statistical Service's request that they mail out the questionnaires and return them to us with no information identifying the respondents' name

or address. The Service directors further indicated that: there would be one mailing of both questionnaires and one reminder postcard; and that the Services would complete telephone follow-up interviews of a random sample of nonrespondents (approximately 50) in each state to examine the issue of potential nonresponse bias. The response rate for the survey was estimated at 45%. To examine the issue of potential nonresponse bias, items from the survey and telephone questionnaires were compared to determine if there were differences in response patterns. No significant differences were found between the two samples with regard to major background variables such as farm size, debt levels, household demographic characteristics and to attitudinal questionnaire items. The two samples (mail and telephone) were then combined for each state and a regional data set, consisting of 4,087 production questionnaires and 3,630 partner questionnaire, was created.

5. About 10% of Midwest and 8% of the Ohio sample are aged 70 or older. We included these respondents in Tables 1,2, and 3 because: each sample is based on the presence of a respondent who defines him/herself as currently operating a farm for the study year; and some farm people over age 70 have off-farm jobs. The figures reported in the table differ little (1-2%) when respondents aged 70 or over and respondents intending to retire from farming are excluded.

6. Studies that link historical context to households and individuals typically cannot do so directly and must infer that individuals' hardships experienced were related to the macroeconomic environment. Such studies "emphasize the ways that larger social structural forces constrain, and to some extent determine, the repertoire of adaptations available to individual families in a given society. These social structural forces have impact not only on the adaptations that are possible, but also on which families — and which individuals within families — receive the most benefit from a given strategy" (Moen & Wethington 1992:243). Macroeconomic contexts thus are seen as an opportunity structure, circumscribing as well as differentially impacting individuals and households. In the present study, we use farm-household conditions to indicate varying positions within farm households that form the basis for members' labor allocations during the crisis. While we recognize that due to the nature of survey research, these conditions cannot be linked directly to the macro-level crisis, we believe that they do at least implicitly capture crisis effects for the following reasons. First, the purpose of both the Ohio and Midwest surveys were stated to the respondents as being conducted to assess the impact of the farm crisis. Second, for the Ohio survey, we specifically phrased all questions measuring household adjustments, dissatisfaction with finances, and perceptions of household hardship — in terms of "changes made due to financial strains" in recent, past years. Items measuring financial conditions — debt-to-asset and income also refer to the past year (1987) while the dependent variables are 1988 data. We thus use retrospective data to tap crisis experiences. While sociologists acknowledge that retrospective data can be problematic due to personal memory, the temporal period was the recent past (generally one to three years), so that this should minimize such issues. Third, unlike many studies that examine period effects only, through examining positions as well, we are able to control for factors extraneously related to the crisis, that could have affected "enterprise-household financial conditions," such as age number of children, and all farm structure variables.

7. The debt-to-asset ratio is a commonly used indicator of financial solvency and reflects the risk associated with the operations' financial structure. However, analysts caution that it is only one measure of a farm's financial conditions: it does not take into account how debt is structured which influences a borrower's ability to service and repay; debt service commitments may be met with earnings which vary by household; and as noted, in the case of the Ohio sample, the debt-to-asset ratio is associated with farm size, with larger farm more highly leveraged but also generally more able to service debt. The debt-to-asset ratio thus should be used in combination with other income and farm size measures, as we have in the regression analyses. The mean debt-to-asset ratio for 1987 was 19% as compared to 15% for the nation (Morehart et al. 1988:134). There is no indication that Ohio farmers became financially stressed in 1987 due to land purchases as we examined the zero-order correlation between the debt-to-asset ratio and a question about purchases of land in the recent past. Our data also indicate that the debt-to-asset ratio taps financial stress for our population. Farmers with debt-to-asset ratios over 40% were significantly more likely to have: increased farm and off-farm work; greater dissatisfaction with farm finances; made more household adjustments; experienced

greater economic hardship; and higher role stress. Those with higher debt-to-asset ratios are also more likely to work off-farm and to have a spouse who does so.

8. We follow Simpson et al. (1988) and Buttel and Gillespie (1984) by including time spent in farm work as an independent variable in the models for farm work; and by including time spent in off-farm work as a determinant of the amount of time spent in farm work. Reasons for this noted by the above studies are: to control for labor time spent in another work domain; to test for gender differences in these relationships. Including these variables is also relevant due to patterns of labor allocation observed during the farm crisis: farm women and men were said to increase total work hours, both on the farm and off-farm, which, in turn, compounded personal and family stress. Since our analysis collects only cross-sectional data on the independent variables, we are unable to ascertain causality. Rather, our focus is limited to delineating characteristics that are related to patterns of work and changes in work during the crisis period. However, it should be noted that most independent variables tapping household enterprise financial conditions and enterprise and demographic characteristics were framed to the respondent as causally prior to the dependent variables or could be considered causally prior, such as capital ownership.

9. We performed additional analyses to include variables on the extent of landownership and the availability of other family labor. Adding these variables to the regression models in Tables 5, 6, and 7 resulted in no significant relationship with any of the dependent variables nor did these variables alter any of other relationships in these models. We also performed analyses adding variables about the respondents' spouse. In this case, the relevant analyses would be for the 86% of the sample that is couples only. We created new variables for men and women adding their spouses' perceptions of economic hardship, amount of farm labor performed, and changes in farm and off-farm work. While spouses' variables have some influence on respondents' labor allocations and stress, all relationships reported in Tables 5, 6, 7, stay the same when the above variables are added and the sample is confined to only couples.

10. Specification of the models for stress follows analyses presented in previous tables. This allows us to control for all variables that might affect changes in labor allocations, in turn, permitting the direct effects of these variables on stress to be measured. The contextual variables are kept in this last analysis for reasons of continuity. The types of variables in the model for stress are those that have been used previously in studies of nonfarm populations (e.g., economic hardship and demographic variables) and have been used as well in studies of farmers during the crisis. Contextual variables are not often included in models of stress, although there is increased recognition that they should be (Aneshensel 1992; Wagenfeld et al. 1993). In brief, local context has been seen as providing economic resources, social support, and a normative environment which affects stress. In the sociological literature, a longstanding conceptual argument has been that areas which are more urbanized or less rural offer a normative environment associated with additional stressors. Similarly, areas where a higher proportion of women are in the labor force may be related to lower personal stress if one considers this an indicator of the normative work environment, economic resources, and opportunities.

Attitudes, Values, and Entrance into Cohabitational versus Marital Unions*

MARIN CLARKBERG, *University of Chicago*
ROSS M. STOLZENBERG, *University of Chicago*
LINDA J. WAITE, *University of Chicago*

Abstract

This article argues that marriage and cohabitation are associated with important differences in work patterns, earnings, treatment of money, use of leisure time, social relations with the extended family, the division of household labor, and fertility. We hypothesize that these differences lead those considering the formation of a household to consider their attitudes toward these aspects of life, which appear to be so different in marriage from those in cohabitation. Using data from the National Longitudinal Study of the High School Class of 1972, we test and find support for the hypothesis that the choice between cohabitation and marriage is affected by attitudes and values toward work, family, use of leisure time, money, and sex roles, as well as values and attitudes toward marriage itself.

Cohabitation is now an important form of union formation in the U.S. Recent estimates suggest that about 35% of those born in the early 1960s will live with someone of the opposite sex before age 25 compared to less than 8% of those born in the early 1940s (Bumpass & Sweet 1989). Although cohabitation is now unexceptional, key questions remain about why some who form households establish cohabitational unions while others marry. This article argues that the choice between marriage and cohabitation impinges on a wide range of activities, circumstances, and social relations. These most obviously include procreation and relations between cohabitants or spouses, but we argue that they also comprise relations with extended family, leisure pursuits, employment, division of economic resources, and division of household labor. Cohabiting may allow individuals or couples who feel unready for the demands of marriage to delay the assumption of marital roles but to acquire the benefits

of coresidence. Consequently, we hypothesize that the choice between cohabitation and marriage for first union is affected by attitudes and values toward work, family, use of leisure time, money, and sex roles, as well as values and attitudes toward marriage itself. To explore this general hypothesis, we apply discrete-time event-history methods to data on the marriage and cohabitation patterns of male and female respondents to the National Longitudinal Study of the High School Class of 1972.

Background: Cohabitation versus Marriage

Unmarried cohabitation (hereafter "cohabitation") in the past was often called "common law marriage" and often has been treated as simply a briefer (Willis & Michael 1994) or less legalistic (Teachman & Polonko 1990; Teachman, Thomas & Paasch 1991) variety of marriage. However, recent longitudinal evidence indicates that values and attitudes toward marriage affect the propensity of individuals to form cohabitational unions (Axinn & Thornton 1992). Other studies (discussed below) report substantial differences between the individual characteristics, time-use patterns, and values and attitudes of married and cohabiting persons. Interpersonal dynamics of marriages and cohabitational unions also have been found to differ. However, some of the most suggestive of these analyses are based upon cross-sectional data that cannot distinguish the effects of attitudes and values on cohabitation from the effect of cohabitation on values and attitudes (e.g., Bumpass, Sweet & Cherlin 1991; Lesthaeghe & Surkyn 1988; Rindfuss & VandenHeuvel 1990; Thomson & Colella 1992). Some key findings follow.

TIME USE

Economic and sociological theories often conceive of marriage as an institution in which the pursuit of individual goals is replaced by joint utility-maximization by husband and wife (e.g., Becker 1991; Parsons & Bales 1955). Some of these goals are merely joint versions of individual goals, such as obtaining food, shelter, and other necessities. Other goals can exist only in the context of couple relationship, such as childbearing (Rindfuss & VandenHeuvel 1990) and fidelity (Caplow, Bahr & Chadwick 1983) or are correlated with marriage, e.g., regular religious attendance and home ownership (Caplow, Bahr & Chadwick 1983; Rindfuss & VandenHeuvel 1990). In theory, replacement of individual objectives by joint goals changes the time allocation patterns of actors; empirical studies (cited below) find that it does so.

Many time-use group studies amalgamate cohabitors with single persons and therefore can only suggest differences between cohabitors and married persons. But this literature does indicate that time spent on work, housework, and leisure all vary substantially by marital status (Juster & Stafford 1985). Most notable is time spent in the labor market: married men spend significantly more time in the labor market than single men and married women spend significantly less than their single counterparts (e.g., Juster & Stafford 1985; Shelton 1992). Women's time in the labor market drops as their time spent in housework increases: even among employed women, marriage increases time spent on

household labor by a third or more (Shelton 1992; South & Spitze 1994). Even in two-profession couples where both partners devote similar numbers of hours to paid labor, wives are still far more likely to change or leave jobs due to a geographic change in husbands' place of work than vice-versa (Bielby & Bielby 1992). And finally, while single and married women spend comparable amounts of time on leisure activities, men experience large drops in leisure time, particularly active leisure, with marriage (Juster & Stafford 1985; Shelton 1992).

Empirical studies find that cohabitors segregate household tasks less by gender than do married people (Blair & Lichter 1991). And while female cohabitors still spend more time on housework than male cohabitors, male cohabitors spend more time on housework than either single men or married men, and cohabiting women spend less time at housework than married women (South & Spitze 1994). To the extent that husbands do contribute to housework, their efforts are often considered "helping out" and their wives typically continue to have primary responsibility to ensure that the task is carried out (Berk 1985; Hochschild 1989). In addition, cohabitors spend less time on religious activities than married persons (Stolzenberg, Blair-Loy & Waite 1995; Thornton, Axinn & Hill 1992). And Blumstein and Schwartz (1983) note that "Cohabitors feel most strongly about having time away from their partners . . . [and] have the clearest sense of a need for personal time. . . . Their belief in personal independence . . . encourages them to maintain separate lives" (186).

INTERPERSONAL DYNAMICS

Focusing more on cohabitations and marriages than on the individuals who cohabit and marry, Brines and Joyner (1993) and Blumstein and Schwartz (1983) argue that cohabitational unions are bound together by egalitarian individualism instead of the joint utility maximization that characterizes marriage in its widely accepted models (Becker 1991; see also Parsons & Bales 1955). Blumstein and Schwartz (1983) find that cohabitors tend to explicitly agree that both partners should contribute equally to all areas of their relationship. Brines and Joyner (1993) find that income inequalities between partners tend to destabilize cohabitations while doing the opposite to marriages. This finding led Brines and Joyner to conclude that "marriage and cohabitation differ not merely by legal status or by the attributes of partners, but also by the internal processes that promote cohesion" (35).

INDIVIDUAL CHARACTERISTICS

Rindfuss and VandenHeuvel (1990) argue that cohabitors are more likely to describe themselves as "never married" than "married" and to have nonfamilial activity patterns and home ownership rates more characteristic of unmarried noncohabitors than of married persons. Fertility patterns of cohabitors differ substantially from those of the married (Bachrach 1987). Cohabitors differ from married persons in demographic characteristics such as race, ethnicity, income, and education (Bumpass & Sweet 1989; Glick & Spanier 1980); illicit drug use (Yamaguchi & Kandel 1985); employment experience (Clarkberg 1994); and even "personality problems" (Booth & Johnson 1988).

VALUES AND ATTITUDES

Lesthaeghe and Surkyn (1988) and Lesthaeghe, Moors, and Halman (1993) find that cohabitors are less likely than married persons to disapprove of marital infidelity and divorce. Cohabitors are less inclined than married persons to espouse traditional gender roles (Lesthaeghe & Surkyn 1988) and more likely to stress the importance of individual freedom within marriage (Thomson & Colella 1992). Compared to married persons, cohabitors expect fewer children (Rindfuss & VandenHeuvel 1990), express less commitment to an ideal of marital permanence (Axinn & Thornton 1992; Bumpass, Sweet & Cherlin 1991; DeMaris & MacDonald 1993), and are less attached to the principle of marital sexual fidelity (DeMaris & MacDonald 1993). Studies by Axinn and Thornton (1992) and Thornton, Axinn, and Hill (1992) are particularly noteworthy because they use longitudinal data to examine the effects of religiosity and attitudes toward divorce on the propensity to subsequently cohabit or marry. These analyses find that a person's religiosity and disapproval of divorce have positive effects on the probability that his or her first union is a marriage rather than an unmarried cohabitation.

Hypotheses: Attitudes and Values

Although little of the previous research on the determinants of cohabitation supports strict causal interpretation, the literature reviewed above suggests that cohabitation and marriage are associated with large differences in work patterns, earnings, treatment of money, time use, leisure, social relations with extended family, the division of household labor, fertility, and perhaps other things too. The well-defined and often sex-typed roles and responsibilities of ideal marriage contrast sharply with the emphasis on equality, independence, self-reliance, and self-determination that seems to characterize cohabitation. These differences lead us to believe that rational people contemplating formation of a household would consider their attitudes toward the aspects of life that appear to be so different in marriages from those in cohabitations. Other things equal, these people would choose to marry or cohabit, depending upon the extent to which marriage or cohabitation appears more likely to produce their current preferred patterns of time use, contact with relatives, work, leisure, and so on.

Cohabitation tends to be a relatively short-lived union. Most cohabiting couples either marry or separate within only two years (Bumpass & Sweet 1989). But some who wish to marry eventually may prefer to delay the assumption of marital roles, we argue, precisely because they value leisure time, money, career success, or other goals not compatible with marriage in the short run. Thus, some individuals may, because of their attitudes and values, enter a cohabitation as a step toward marriage, but one that offers them more freedom in the short term than marriage would. Others may prefer never to assume the breadwinner or housewife role and may prefer long-term cohabitation for this reason. But in both cases, current attitudes and values toward time use, interpersonal relationships, career, and money affect the chances of forming a

union and the choice to marry directly or cohabit, perhaps in anticipation of later marriage.

Thus, we hypothesize that attitudes and values toward work, family, use of leisure time, money, and sex roles — as well as values and attitudes toward marriage itself — all affect the probability that an individual who forms a household for the first time will do so as a cohabitation rather than a marriage.[1]

IMPORTANCE OF MARRIAGE, FAMILY LIFE, AND TIES WITH EXTENDED FAMILY

Others (e.g., Axinn & Thornton 1992; Bennett, Blanc & Bloom 1988; Willis & Michael 1994) suggest that the relative instability of cohabitational unions makes them well suited to those who wish conjugality without long-term commitment. Childbearing implies long-term commitment, as does maintenance of ties with extended family. So we hypothesize that the propensity to marry rather than to cohabit is increased by values and attitudes that are favorable to marriage, childbearing, and maintenance of ties with relatives.

SEX-ROLE LIBERALISM

Traditional sex roles are differentiated, with women's roles centered on household and children, and men's roles centered on economic activity outside the home (England & Farkas 1986). Sex-role traditionalism refers to a preference for these differentiated roles, while sex-role liberalism indicates a preference for less differentiation between men's and women's roles, and less segregation of roles by sex into home- and work-centered activities. We hypothesize a negative effect of sex-role liberalism on the probability of marriage as opposed to cohabitation.

IMPORTANCE OF LEISURE

Marriage increases hours of employment for men and hours of housework for women, and childbearing makes heavy demands on the time of parents (Juster & Stafford 1985). So it appears that marriage provides less time for leisure pursuits than cohabitation. We hypothesize that attitudes and values that favor leisure time reduce the probability of marriage as opposed to cohabitation.

IMPORTANCE OF MONEY

Marriage is associated with childbearing and child rearing, which are exceptionally expensive. Marriage is also more associated than cohabitation with home ownership, and that too is very expensive. Even in the absence of children and home ownership, men may view marriage as a financial drain because marriage (but not usually cohabitation) gives spouses claims on each others' earnings, and women not only tend to earn less than men, but women's earnings tend to decline after marriage (England & Farkas 1986). In contrast, the same gender inequality in earnings may make marriage more attractive, or just less unattractive, to women who seek money, since the labor market provides females with opportunities for smaller average earnings than it gives to men and marriage tends to increase their income, while it decreases the income of males. So we

hypothesize that attitudes and values that favor an abundance of money tend to lower the probability of marriage as opposed to cohabitation. We hypothesize that this effect is larger for men than for women.

IMPORTANCE OF CAREER SUCCESS AND WORK

Because marriage increases men's average hours of work (Juster & Stafford 1985) and wages (Daniel 1992), marriage appears to be compatible with men's efforts to build successful careers. This tendency to increase hours of work after marriage has been found even for men who cohabited before marriage, suggesting that the marriage is more compatible than cohabitation with hours of work. Further, men who marry tend to have some of the burden of housework lifted by their wives, thereby enabling husbands to trade housework for time on the job. We therefore hypothesize that for men, attitudes and values that favor job and career success tend to raise the probability of marriage as compared to cohabitation.

For women, we expect the opposite effect of attitudes and values that favor job and career success. Marriage appears to be a hindrance to paid employment by wives and married women tend to work fewer hours for pay than their husbands, due at least in part to the disproportionate share of household and child-rearing tasks born by most wives (Coverman 1983). So we hypothesize that for women, attitudes and values that favor job and career success tend to lower the probability of marriage as compared to cohabitation.

CONTROLS FOR OTHER INFLUENCES ON UNION FORMATION

All our hypotheses are subject to the stipulation that relevant "other things" that affect union formation are held constant. These things are correlates of work, leisure, money, family, and sex-role attitudes and other values that affect nuptiality and household formation patterns, including race (Bumpass & Sweet 1989), sex, religion of upbringing (Thornton, Axinn & hill 1992), parental characteristics (Bumpass & Sweet 1989), years of schooling and school enrollment (Thornton, Axinn & Teachman 1994), employment, income, and age. Because most contemporary American religions encourage marriage and strongly discourage cohabitation, and because time spent in religious activities has been shown to affect the probability of cohabitation (Thornton, Axinn & Hill 1992), it is also appropriate to control for religious activity.

Data

We use data on 12,841 respondents who participated in the 1986 wave of the National Longitudinal Study of the High School Class of 1972 (NLS-72), which was first administered to a nationally representative sample of high school seniors in 1972, when respondents were about 18 years old. Follow-up survey waves were fielded in 1973, 1974, 1976, 1979, and 1986. The 1986 wave included extensive individual histories of marriages and cohabitations up to the age of approximately 32 years. Data from this fourteen-year span permit analysis of first union formation from late adolescence through the early thirties, a

"demographically dense" (Rindfuss 1991) time of life in which the vast majority of first coresidential unions are formed. To permit the discrete-time event history analyses with time-varying covariates that we describe below, the longitudinal NLS-72 data were reorganized into a file of person-year records, with one record for each person in each year, rather than a single record for each person in the sample. Because October is the reference month for many NLS-72 variables, each year begins in October and ends the following September.

MARRIAGE AND COHABITATION MEASURES

The 1986 wave of the NLS-72 gathered extensive retrospective marriage and cohabitational histories. These histories include the starting and ending dates of up to three marriages or "marriage-like relationships" lasting one month or more (85% of respondents reported at least one such union; 55 individuals reported more than three).[2] For each relationship, respondents were asked the date of the start of the relationship and whether they were married to the person when they started living together. For each respondent in each year between 1972 and 1986, we construct two dummy variables: the first is an indicator for the start of a first union during the year; the second is a dummy variable set to one if the union was a cohabitation and zero else.

ATTITUDE MEASURES

In each wave of NLS-72, respondents were given a list of activities and goals, and asked "How important is each of the following to you in your life? Very Important, Somewhat Important, or Not Important?" Six items on this list correspond to attitudes and values listed among our hypotheses: (1) "Finding the right person to marry and having a happy family life," (2) "Living close to parents and relatives," (3) "Being successful in my line of work," (4) "Being able to find steady work," (5) "Having lots of money," and (6) "Having leisure to enjoy my own interests."

Sex-role liberalism is measured on a scale obtained by factor analysis of responses to ten Likert scale questions on sex-role attitudes that appeared in the 1976 and 1979 survey waves. These items and their factor analysis are described in Appendix A. In both waves, the factor *liberalism of sex roles* correlates about -0.8 with the extent of agreement with the statement "It is better for everyone if the woman stays home and the man goes out to earn a living." A higher factor score indicates more acceptance of nonfamilial roles for women.

CONTROL VARIABLES

Control variables are listed in Table 1. Control variables are "fixed" if their values cannot vary between 1972 and 1986, and "time-varying" if their values can change during this time. Fixed controls include sex, religion in which the respondent was raised, race, and parental characteristics. Sex effects are controlled by performing all analyses separately for males and females. Religion is represented with dummy variables for Catholic religion and Other Christian religion.[3] A third dummy for any other religion, a category dominated by

Protestants and including no religion, is omitted from analyses to avoid multicollinearity. Race is represented with a dummy variable for black. Parental characteristics include the natural logarithm of the parents' annual income in 1972, the mean years of school completed by the respondent's parents, and a dummy variable equal to one if the respondent was raised in an intact family (living in a household with both natural parents in the senior year of high school).[4]

Time-varying controls include years of school completed, the natural logarithm of current earnings, a dummy variable equal to one if the respondent reported having had a child, and dummy variables for current school enrollment, current employment, and current membership in a church.[5] Age is held constant by performing separate analyses for 18-22-year-olds and for 22-31-year-olds, and by including variables for the calendar year and the calendar year squared.

Statistical Methods

Two key features of our hypotheses shape our choice of statistical method. First, the hypotheses concern the occurrence of the events marriage and cohabitation and that suggests the use of event history techniques. Second, our hypotheses are about attitudes. Attitudes can vary over time, and that variation should be recognized in the analysis to the extent possible. Although surveys can measure attitudes at specific times, and pairs of longitudinal survey waves can establish intervals during which attitudes change, surveys cannot identify the precise times between interviews when change occurs.[6] So we use a logistic regression discrete-time event history model. This technique approximates results from continuous-time proportional hazards models (Allison 1984; Yamaguchi 1991) while easily permitting covariates to vary over time and accommodating the unavailability of continuous time measures of attitudes and other key variables.

Our dependent variable involves three competing states — single, cohabiting, married — which makes analysis slightly more complicated than most two-state event history models. Following Allison (1984), Yamaguchi (1991), and Agresti (1990), we use the method of continuation-ratio logit models to examine these events. That is, we perform two logistic regression analyses: The first analysis is based on all person-years that begin with the respondent in a never-married, never-cohabited state. The dependent variable is the dummy variable for formation of a first coresidential union in the year. The second analysis is based on all person-years in which individuals formed a first marriage or first cohabitation. In this second analysis, the dependent variable is a dummy variable for cohabitation. This second model allows us to differentiate those who choose marriage from those who choose cohabitation.

For each person-year, time-varying variables are measured in the most recent previous year for which data are available. Using attitude measures from previous time intervals avoids the possibility that observed attitudes could be the result of residential union formation behavior in the interval under consideration. This lag reduces the reliability of attitude measures, we suspect, but that reduction would bias coefficients downward, making our hypothesis

TABLE 1: Definitions of Independent Variables

Name	*Definition*	*Range*	*Years Measured*
Marry	Importance of "finding the right person to marry and having a happy family life"	1-3	72-74, 76, 79
Close to parents	Importance of "living close to parents and relatives"	1-3	72-74, 76, 79
Success	Importance of "being successful in my line of work"	1-3	72-74, 76, 79
Steady work	Importance of "being able to find steady work"	1-3	72-74, 76, 79
Money	Importance of "having lots of money"	1-3	72-74, 76, 79
Leisure	Importance of "having leisure to enjoy my own interests"	1-3	73, 74, 76, 79
Liberalism of sex roles	Factor scores measuring sex-roles liberalism	-3.1-2.2	76, 79
Black	Indicator for black	0-1	
Catholic	Indicator for Catholic	0-1	72
Other Christian	Indicator for "other Christian"	0-1	72
Religion	Indicator for church membership	0-1	76, 79
Parental income	Natural log of parental income	8.4-10.3	72
Imputing income	Indicator for imputing a value on *parental income*	0-1	72
Parents' education	Mean of parents' educational attainments	10-18	72
Intact family	Respondent living with both natural parents in 1972	0-1	72
Educational attainment	Number of years of schooling completed	11-20	72-85
Student	Indicator for enrollment in school	0-1	72-85
Working	Indicator for employment	0-1	72-85
Child	Indicator for presence of a child or children	0-1	72-85
Income	Natural log of respondent's total income	0-11.9	72-85
Year	Year in pooled-interval of person-year record	72-85	72-85
Year square	Square of *year*		

tests conservative.[7] For two reasons, we perform separate analyses for person-years corresponding to ages 18 through 22 and 23 through 31. First, others find that union formation varies substantially by age (e.g., Goldscheider & Waite 1986; Waite & Spitze 1981). And, second, some attitude measures are available only at later ages: attitudes toward leisure was not included until the 1973 survey wave, and sex-role attitudes were not included until the 1976 wave. We present estimates of models with and without these variables for the later ages to allow comparison with models for the younger ages.

Logit coefficients lack an intuitively appealing metric, so we transform the logit coefficients for each attitude or value measure into the change in probability of union formation associated with a specified increase in that variable. For example, a two-unit change in the variables *marry, closepar, success, steady work, money,* or *leisure* is a change from reporting that the corresponding aspect of life is "not important" to reporting that it is "very important." These effects are nonlinear and nonadditive; we evaluate them at the average probability level for each subsample in which data are analyzed (Peterson 1985; Stolzenberg 1979).

Note that the two dependent variables in our analysis differ in an important way. The model of union formation estimates the effect of various attitudes and values on the probability of forming a first union during a year, given that one had not done so at the beginning of the year. Although most individuals have formed a first union by the age of 31, the proportion forming a union in any particular year is small, varying between 9 and 14%, according to age and sex (see Table 2). Thus, substantively modest effects on the probability of union formation in any year could cumulate over a number of years to a quite sizable impact on the outcome. These effects can be viewed as affecting the speed with which young men and women enter a first coresidential union.

The second set of models estimates the effect of attitudes and values on the type of first union chosen, whenever this choice is made. Clearly, one can decide whether to enter a union this year over a number of separate years, but one decides on the type of union — given that one is entered — only once. The mean proportion cohabiting in first union, given in Table 2, varies from 22 to 37%, according to age and sex.

Logit effects, of the type we describe above, are small when the mean probability of the relevant outcome is small, as is the case for the annual probability of union formation. The same coefficient would imply a much larger effect on an event, such as cohabitation versus marriage in first union, which has a mean probability between .25 and .75. Untransformed logit coefficients for key variables are presented in Appendix B and these allow comparison of the size of effects in subgroups having different mean probabilities of the outcome in question.

Results

Complete results of all logistic regression analyses appear in Appendix B. Table 2 gives the effects of variables directly related to our hypotheses, transformed into probability differences associated with a two-point or one standard deviation change in the independent variable, as appropriate.

TABLE 2: Effects of Attitudes toward the Family, Work, Money, Leisure, and Sex Roles on the Annual Probability of Forming a First Union, and Probability that the First Union Is a Cohabitation[a]

[a] Based on logistic regression models reported in Appendix B. The effects of *marry, close to parents, success, steady work, money,* and *leisure* result from a two-point increase on the three-point scale in which 3 = "very important," 2 = "somewhat important" and 1 = "not important." The effect of *liberalism of sex roles* results from an increase of one standard deviation in the sex-role attitude factor score.

One-tailed: * $.01 < p < .05$ ** $.001 < p < .01$ *** $p < .001$

MARRIAGE AND FAMILY

Table 2 presents effects of a two-unit increase in the importance of "finding the right person to marry and having a happy family life" (*marry*); and "living close to parents and relatives" (*close to parents*). A two-unit change on these three-point scales is a change from a response of "not important" to "very important." The top panel, which presents the effects on the annual probability of forming a first union, shows that for both men and young women, favorable attitudes toward marriage increase the probability of union formation in a given year quite substantially. At the mean, an increase from "not important" to "very important" in *marry* raises the probability that a union is formed in any given year from 9% to 20% for men 18 to 22, and from 13% to 30% for women the same age.[8] Similar effects appear at later ages for men and women in both models examined. But, as hypothesized, if a union is formed, that same two-point increase in the importance of *marry* lowers the probability that the union is a cohabitation from 22% to 7% at younger ages for men and from 22% to just 4% at younger ages for women. The effects on union type are even larger at later ages — for women, there is a significant increase (at the 0.05 level) in the size of the effect of *marry* across the ages examined. Thus, the substantive effects of changes in the reported importance of marriage are quite large for both speed of entry into a first union and for the type of union chosen.

Note, however, that wanting to live close to parents and relatives slows the transition to first union for both men and women at all ages; a two-point increase in *close to parents* would decrease the probability of a first union in any given year by about 2%. For men 18 to 22, for example, this would mean a decline from 9% to 7% in the probability of entering a first union. In retrospect, it appears that this measure may reflect attachment to family of origin rather than an interest in family formation.

Table 2 also supports the hypothesis that among those who form first unions, persons who place high value on living close to parents and relatives (*close to parents*) are less likely to cohabit than to marry. However, these negative effects are not statistically significant for 18-22-year-old males and are one-half to one-third the size of corresponding effects of *marry* for women and 23-31-year-old men. These effects are sometimes substantively important, however; a two-point increase in the importance of living close to relatives would reduce the chances of cohabiting at first union by 11 to 14% for women at all ages and for men at later ages. Thus, for women from 18 to 22 years old an increase in importance of living close to relatives would reduce the probability of cohabitation rather than marriage from 22 to 11%, with similar changes for older women and older men.

MONEY AND WORK

The third through fifth rows of Table 2 present effects of *success* (importance of "being successful in my line of work"), *steady work* (importance of "being able to find steady work"), and *money* (importance of "having lots of money"). We hypothesized that men for whom career success is important would find the traditional male breadwinner role more comfortable than would men who do

not value career success for themselves. For men, *success* and *steady work* have very small, statistically insignificant effects on the probability of union formation. For men who do form a first union, both *success* and *steady work* decrease the chances that it is a cohabitation rather than marriage at both young and later ages, but only the effect of *steady work* for 23-31-year-olds is statistically significant. For these men a two-point increase in the importance of steady work would decrease the probability of cohabitation from 34% to 20%, a finding that is consistent with our hypothesis.

We also hypothesized that the importance of money would reduce the probability of marriage. Attitude toward money, for men, has effects that are statistically significant, negative, and modest in size; the effects in Table 2 imply that a two-point increase in the importance of money would decrease the annual probability of a first union for men from 9% to 7% at younger ages and from 13% to 11% at later ages. Table 2 shows that a two-point increase in the importance of money would increase the probability that a first union is a cohabitation from 34% to 43% for older men, as we hypothesized. However, *money* shows no effect on the probability of cohabitation at younger ages for men. Thus, the importance of money seems to reduce union formation for men and — at least among older men — to reduce the probability of marriage over cohabitation for those forming a union.

We hypothesize that women for whom personal career success is important would find the traditional wife role implied by marriage to be less attractive than would women for whom career success was not important. Career-oriented women would, we hypothesized, be less likely to enter a union than other women and more likely to cohabit if they did form a union. Table 2 shows negative effects of *success, steady work,* and *money* on the probability of first union formation for younger and older women, although these are all small and only two of the three variables reach statistical significance and then only at the younger ages. For women 18 to 22 years old, the importance of success at work and steady work reduce the probability of union formation. For these young women, an increase of two points in the importance of steady work decreases the annual probability that they form a union from 13% to 10%. A two-point increase in *success* decreases the annual probability from 13% to 11%. These effects are significantly different (at the 0.05 level) than the effects for men, which run in the opposite direction. We see no significant effect of *money* on women's union formation probabilities.

If women do form a union, we see effects of the type we hypothesized; the importance of career success increases the probability of choosing cohabitation. For 18-22-year-old women who do form a first union, the probability that the union is a cohabitation is unaffected by *success* and *steady work,* but *money* shows a small positive effect on the probability that the union is a cohabitation. A two-point increase in the importance of money implies an increase from 22% to 28% in the probability that the first union is a cohabitation. For 23-31-year-old women, a two-point increase in the importance of success at work raises the chances of cohabitation at first union from 37% to 57%, an effect that opposes the direction of and is significantly different from the effect for men at the same age. The same increase in the importance of money raises the probability of

cohabitation from 37% to 52%. These effects are large enough to be important substantively.

These results are generally consistent with our reasoning that men and women for whom traditional expectations about marriage fit well with their personal values are more likely to marry than others. Although the expected effects do not appear for all measures of values toward career or money, those results that do appear consistently show the expected sign and some are substantively important.

LEISURE

We hypothesized that because rather large differences appear in the leisure time of married versus unmarried men, those men to whom leisure time for their own pursuits is important may find marriage relatively unappealing for that reason. The sixth row of Table 2 presents effects of *leisure* for men and women 23 to 31 years old (this measure is not available at earlier ages). *Leisure* has small positive effects on the annual probability of union formation for both men and women. If a union forms, for women *leisure* has no significant effect on the probability that the union is a cohabitation. But for men who do form a union, a two-point increase in the importance of *leisure* increases the probability that the union is a cohabitation from 33% to 53%, which is quite consistent with our hypothesis and suggests important differences between marriage and cohabitation in expectations about allocation of leisure time.

SEX-ROLE ATTITUDES

We hypothesized that those men and women with relatively liberal views of sex roles would be attracted to cohabitation because of its typically less sex-linked division of labor than that associated with marriage. Recall that the measure of sex-role attitudes is available only at later ages. Table 2 shows small effects of sex-role liberalism on the annual probability of forming a first union for women but not for men. However, for both men and women who form a union we see fairly sizable effects of sex-role liberalism on the probability that the union is a cohabitation. A one-standard-deviation increase in sex-role liberalism would increase the probability of cohabitation versus marriage from 33 to 43% for men and from 37 to 49% for women. A comparison of the two models for women at later ages shows that some of the impact of *success* and *money* is mediated through sex-role attitudes. Thus, as might be expected, women to whom career success is important also hold relatively liberal views of sex roles. The results show, as we hypothesized, that men and women who reported relatively liberal views of sex roles prior to first union seem to take those views into account in deciding on the type of union to enter later.

Conclusions

This article argues that marriage and cohabitation provide those who enter them with different sets of expectations for a wide range of activities, circumstances, and social relations. We focus here on relations with extended family, leisure pursuits, employment, division of economic resources, and the division of household labor. We test and find support for the hypothesis that the choice

between cohabitation and marriage is affected by attitudes and values toward work, family, leisure time-use, money, and sex roles, as well as values and attitudes toward marriage itself.

For several reasons we think that our measures of attitudes and values are biased against showing effects on union formation and choice of marriage versus cohabitation. First, our measures of attitudes and values precede our observations of union formation by as much as seven years, especially at later ages. Attitudes and values may change over time and old attitudes tend to have a weaker relationship to current behavior than do current attitudes (McGuire 1985). Second, our measures of attitudes and values — evaluative research attitude measures — are the type least likely to show empirical relationships with behavior; they tell us what people think is good rather than what they are prone to do (Ajzen & Fishbein 1980; Stolzenberg 1994). Given this bias against finding effects and certainly against finding strong effects, we think that the consistent pattern of results, combined with the sizable substantive impact of some measures, provides support for our hypotheses.

At a glance, the similarity between cohabitation and marriage is apparent: they are both romantic coresidential unions. However, researchers faced with a large and persistent empirical association between premarital cohabitation and subsequent divorce have postulated that the cohabiting population is a "select" group — particularly in terms of having liberal values (Axinn & Thornton 1992; Lesthaeghe & Surkyn 1988; Thomson & Colella 1992). These liberal values, we suggest, represent more than a general political orientation. Rather, we argue that these values are indicators of preferences for a kind of union with distinctly different characteristics than marriage. Our results are consistent with the idea that cohabitation is attractive as an alternative to marriage not only because it is a tentative, nonlegal form of a coresidential union but, more broadly, because it accommodates a very different style of life.

A sizable proportion of cohabiting couples eventually marry. For these couples cohabitation may allow them to delay rather than avoid the assumption of marital roles. Certainly, some young adults avoid marital roles that they would currently find constraining or burdensome by avoiding any union. We argue here that cohabitation as an institution allows for flexibility and freedom from traditional gender-specific marital roles, at least temporarily.

Both men and women who reject the constraints and demands of the traditional marriage are more likely than others to choose informal unions. First, our results indicate that those who find marriage in and of itself less important as a life goal are more likely to enter into a cohabitational relationship in their first coresidential union. But even controlling for this, a broad array of attitudes — all associated with marital roles and expectations — affect union formation rates in our models. Beyond one's own attachment to marriage, for example, our results demonstrate that less attachment to one's parents and other kin also increases the propensity to cohabit. Not only can the family, much like a church (Thornton, Axinn & Hill 1992), reinforce pro-marriage values and discourage their ranks from cohabiting, but the "work of kinship" and family cohesion is, in itself, a part of marital roles (Di Leonardo 1987). Those who wish to distance themselves from their families may prefer to avoid the expectations of kin bonding that marriage often places upon them.

Work and the division of labor within the family is, of course, one of the most prominent normative elements of marriage. Our results indicate, then, that men who don't think that success at work or being able to find steady work for themselves is important are drawn disproportionately toward cohabitation, with its egalitarian pattern of responsibility for financial support. And women who value money and career success for themselves are also drawn to cohabitation, which may give them the freedom to pursue their goals unfettered by a need to make accommodations to husbands' careers. But very young women — those 22 years old and younger — tend to avoid any union if they value their own career success, perhaps to allow themselves the freedom to concentrate their energies on schooling and the transition to work, perhaps to retain the financial support of their parents.

We note that a focus on "having lots of money" consistently inhibits union formation, although this result occurs in different ways for men and women. A high value placed on money slows men's entry into any union, but for women, it inhibits marriage, not union formation. To the extent that the egalitarian ideal of cohabitation is tempered by the traditional expectations of financial responsibility in dating and marriage, this can be expected; a cohabiting man with money may feel compelled to pay for some expenses for his partner. On the other hand, this traditional assignment of financial responsibility had adverse consequences for women as well — historically, for example, when women married they often lost control of their own financial resources and property to their husbands. But women may feel less compelled to share financial assets with a cohabiting partner than with a spouse, inhibiting marriage by women who value money. Our results suggest that women who find having lots of money important do not tend to find that either living with or marrying a well-to-do man offers a route to this goal; perhaps finding such a man is more difficult than preparing for a career oneself.

The difference in the demands of cohabitation and marriage appear most strikingly in attitudes toward leisure time; other things equal, young men who highly value leisure time to pursue their own interests are much more likely than those less concerned with this issue to choose cohabitation later. Previous research suggests that marriage affects men's leisure quantitatively as well as qualitatively — not only do married men have less leisure time than single men (Shelton 1992), but they are much less likely to spend their leisure time away from their partners (Blumstein & Schwartz 1983). Our results indicate that those who want to preserve their own leisure time do not shun unions in general — rather they choose an informal union that may not carry the stringent requirements for sharing activities that accompany marriage.

Our results suggest that young men and women both see marriage as constraining. Marriage requires men to be successful at their career, hold a steady job, and give up their individual leisure pursuits. For young women, the burdensome demands avoided by some appear to revolve around giving up careers — or at least making them secondary to those of their husbands. For some young adults, the expectations associated with marriage fit well with their personal values. But other young adults appear to reject these goals — and the traditional sex roles that support them — but to not abandon the prospect of a coresidential romantic union altogether.

APPENDIX A: Item Loadings on Sex-Role Attitude Factor, 1976 and 1979[a]

Sex-Role Attitude Item	Loading 1976	Loading 1979
a. A working mother of preschool children can be just as good a mother as the woman who doesn't work.	-.3124	-.4011
b. It is usually better for everyone if the man is the achiever outside the home and the woman takes care of the home and family.	.7119	.7304
c. Young men should be encouraged to take jobs that are usually filled by women (nursing, secretarial work, etc.).	-.0084	-.0170
d. Most women are just not interested in having big and important jobs.	.4449	.4403
e. Many qualified women can't get good jobs: men with the same skills have less trouble.	-.0037	.0128
f. Most women are happiest when they are making a home and caring for children.	.6706	.6448
g. High school counselors should urge young women to train for jobs which are not held mainly by men.	-.0148	-.0498
h. It is more important for a wife to help her husband than to have a career for herself.	.6914	.7307
i. Schools teach women to want less important jobs.	.0198	.0673
j. Men should be given first chance at most jobs because they have the primary responsibility for providing for a family.	.5959	.6348

[a] After exploratory analyses that indicated that a factor structure with two dimensions fits the data well, we performed maximum likelihood factor analysis with a nonorthogonal promax rotation using SAS procedure factor. The two distinct dimensions produced by the factor analysis indicated that the first strongly related to views of traditional male-female roles in the family, and the second related to views of the appropriate means for correcting gender inequality. We estimated all models reported in this article with both factors, but only the first showed significant effects. In 1976, this single, weighted, rotated factor explains 42.8% of the variance in the items and has a Tucker-Lewis reliability coefficient of 0.92. In the 1979, this weighted, rotated factor explain 47.7% of the variance in the items and has a reliability coefficient of 0.93.

Notes

1. We think that the processes that underlie the transition from a cohabitation to marriage, or the transition from a disrupted marriage into cohabitation, may differ in important ways from the processes that determine the choice between cohabitation and marriage for the first union. We examine only the effects of attitudes on the first union.

2. If cohabiting respondents did not characterize their relationship as "marriage-like," they were not coded as cohabiting. We doubt that it was a substantial source of error in the NLS-72. To the extent that this error did occur, it would bias our analyses against our hypotheses that attitudes and values affect the probability of union formation and cohabitation.

3. Possible responses to the religion question were: Protestant; Roman Catholic; other Christian Religion; Jewish; other or Eastern religion; and no religion. The other Christian category appears to be dominated by fundamentalists.

4. Parental income was missing for about a fifth of the respondents. For almost all cases with missing data, we were able to calculate a predicted income based on parental education, father's occupational status, marital history, race and ethnicity, urbanicity and region of the country. We then added an error term to the predicted values so that the variance of the income variable was not changed by imputation (cf. Little & Rubin 1987). We also included a dummy variable to flag this imputation.

5. In 1972, when the respondents were still in high school, the questionnaire did not include a measure of the respondent's income. The base-year survey did, however, include a measure of number of hours a week worked at a job. For the present analysis, we used a rescaled measure of hours of work as a proxy for income in 1972. We suggest that while this technique may be problematic for adults, it is probably acceptable for high school students, since most of the entry-level jobs available to them would be paid by hourly rates at or near the minimum wage. To evaluate whether this imputation procedure made substantial differences in our models, we reestimated all models with and without income measurements. The coefficients for the other variables were virtually unchanged. We also reestimated our models excluding respondents who formed unions before October 1973 (that is, those for whom we did not have an actual income measurement). This did tend to decrease the coefficient for income. Thus, caution should be used when interpreting the coefficient for income in the youngest age group in our analysis, since our imputation procedure has clearly lowered the reliability of that variable.

6. This limitation is caused by the invalidity and unreliability of retrospective survey questions. Except under unusual circumstances, one cannot ascertain the time at which an attitude changed by asking respondents when those changes occurred. For example, imagine asking a person to name the day or month when he or she decided that living close to relatives changed from being "very important" to being merely "important." In contrast, one can use retrospective questions to ascertain the dates of significant life events, such as marriage or cohabitation.

7. Note that the time-lag for variables measured only in survey years, such as the attitudinal items, can be longer than a year. The time-lag is particularly long for the later years included in our analysis, as the last two waves were more than five years apart. Since more remote measurements of attitude are less reliable predictors of behavior (McGuire 1985), we expect that our results may understate the importance of attitudes on union formation, especially in the later years of young adulthood.

8. We calculate these changes in effects by adding the percentage change associated with a two-point increase in the independent variable of interest — in this case *marry* — to the mean annual probability that a union is formed for the relevant age and sex group. For all variables that appear in models for older and younger ages, we use percentage changes for the comparable model.

Migrant Remittances, Labor Markets, and Household Strategies: A Comparative Analysis of Low-Income Household Strategies in the Caribbean Basin*

JOSE ITZIGSOHN, *Brown University*

Abstract

This article analyses the relationship between remittances and the subsistence strategies of low-income households in four capital cities of the Caribbean Basin. The switch to an export-oriented model of development implemented in response to the economic crisis of the beginning of the 1980s deteriorated the labor market conditions in the region, making it difficult to subsist on local incomes. The findings point to the importance of migrant remittances on urban low-income households in terms of the number of households receiving remittances, their importance for the household income, and their effects on labor market participation of the head of the household, as well as additional members. They suggest that remittances are a rational strategy followed by households confronting very difficult labor market conditions.

This article analyzes the effects of migrant remittances on the life and economic activities of urban low-income households in the Caribbean Basin. During the last two decades, labor markets have become internationalized. An increasing number of people have undertaken long journeys and border crossings to find their livelihood in foreign lands, while at the same time helping the relatives they left behind. The Caribbean is one of the regions where migration and

* *The research reported herein was conducted with the support of a grant from the Andrew Mellon Foundation. The project was a collaborative effort between institutions and research teams in each of the countries studied, under the direction of Professor Alejandro Portes of The Johns Hopkins University. The project directors and institutions involved were as follows: Mario Lungo, Central America University Confederation (CSUCA), Costa Rica; Wilfredo Lozano, Latin American Faculty of Social Science (FLACSO), the Dominican Republic; Juan Pablo Perez Sainz, FLACSO, Guatemala; Sabine Manigat, National University of the Republic, Haiti; and Derek Gordon and Patricia Anderson, University of the West Indies, Jamaica. David Lindstrom, George Wilson, Mahua Sarkar, Roberto Gutierrez, and two anonymous reviewers offered generous comments that greatly improved the article. My gratitude to them. The responsibility for the analysis and the content, however, is only mine.* *Direct correspondence to Jose Itzigsohn, Department of Sociology, 112 George St., Box 1916, Brown University, Providence, RI 02912.*

remittances have become extremely important to the subsistence of the low-income sectors. This work examines the effects of remittances on the subsistence strategies of urban households in four capital cities of the region: Santo Domingo, Guatemala City, Kingston, and Port-au-Prince.

Studies of development and remittances tend to focus either on the effects of remittances on the balance of payments or on their "welfare effect" on the population of the labor-sending country (Lundahl 1985; Martin 1991; Straubhaar 1992). Recently, a number of studies have examined the impact of remittances on the development of a small business sector linked to migration in the country of origin (Lopez & Seligson 1991; Portes & Guarnizo 1991). A number of researchers have focused on the effects of remittances on household income and labor market behavior (Funkhauser 1992; Massey et al. 1987; Selby & Murphy 1982), and some of these view migration and remittances as a rational household economic strategy. This article shares this approach in that it analyzes the demographic and socioeconomic characteristics of households that receive remittances and focuses on the importance of remittances for the household income and labor market insertion of household members. The comparative approach helps to distinguish those household processes that are common to the countries of the Caribbean Basin from those that are particular to each country.

An important contribution of this study is to situate the influence of remittances on household strategies within the framework of the socioeconomic crisis that affected Latin America and the Caribbean in the 1980s and the restructuring of the economies and urban labor markets that followed. Decline in local wage opportunities has provided a strong incentive for international migration. The money that migrants send back home is likely to become an important factor in the household budget (Funkhauser 1992; Kaimowitz 1990; Tardanico 1993).

Remittances and Development

A large number of studies on the effects of remittances on development focus on how remittances are spent and the effect of that spending on the economy of the sending country or region. There is no consensus on what those effects are, or how best to evaluate them. The debate centers around the empirical evidence showing that remittances are spent mostly on basic subsistence needs, and after those are fulfilled, on housing improvement and eventually land purchase (Appleyard 1989; Guarnizo 1992; Stahl & Arnold 1986).

Some scholars, mostly economists working from a neoclassical perspective, see remittances as having a positive effect on the development of the labor-sending area. On the macroeconomic level, the argument in favor of remittances asserts that they constitute a much-needed source of foreign currency. Remittances contribute to leveling the balance of payments and pay a large proportion of the import bill of the labor-sending country. Moreover, these scholars claim that despite being spent on consumption, remittances provide an important incentive for the local production of goods and services. Remittances

also improve both income distribution and the quality of life of large segments of the population (Arnold & Stahl 1986; Keely & Tran 1989).

Other scholars, mostly social scientists working from a historical-structural approach, see remittances as increasing the social inequalities in the labor-sending countries. Moreover, remittances are at best an unreliable source of foreign currency, since they depend heavily on the continuation of the labor migration process, thus increasing the dependency of the labor-sending countries on the willingness of the labor-receiving countries to keep receiving migrants (Birks & Sinclair 1980; Kritz & Keely 1981). Remittances do increase the purchasing power of certain segments of the population, changing their consumption patterns to include more imported goods, and creating a demonstration effect among nonmigrant households. Thus, according to this argument, remittances increase inequality, undermine the balance of payments (through increased demand for imported goods), and have inflationary effects. They are also said to cause an increase in land speculation and prices and a decrease in agricultural production (Bray 1987; Grasmuck & Pessar 1990; Martin 1991).

The empirical evidence regarding remittances is inconclusive. Researchers have found evidence of both beneficial and detrimental effects of remittances (Keely & Tran 1989; Grasmuck & Pessar 1991). Straubhaar (1992) analyzes the effects of labor migration and remittances on Turkey during the 1960s and 1970s and finds that at different times and in different regions of the country, remittances have had all the effects described above. A new wave of studies coming from the field of economic sociology are less deterministic in their predictions. These studies see the effect of remittances as dependent on the social capital and social networks of those who migrate and those who remain at home (Guarnizo 1992, Massey et al. 1987). Empirical studies from this perspective have focused so far on the effect of remittances on the development of small businesses in the home country. Under the changes brought on by structural adjustment policies, small businesses have become an important source of employment and an avenue for upward mobility. These studies find that in some cases, the existence of networks among migrants and their relatives at home may help in the development of a sector of small businesses linked to migration (Guarnizo 1992; Portes & Guarnizo, 1991).

The emphasis of the present study is placed on the relationship between remittances and the strategies that low-income households employ for subsistence and for upward mobility. Among the low-income population of the cities in the periphery, households, and not individuals, are the main economic unit. Women's wages are usually too low to enable female-headed households to live on one income. Men's earnings are higher, but they seldom allow the household to achieve desired patterns of consumption and recreation. It is the pooling of household resources that allows the low-income population to "make it" in cities ravaged by underemployment and unemployment (Roberts 1989). Households can try to cope with a deteriorating economic situation by sending additional household members into the labor market, decreasing their budget expenses, or allowing the migration of one or more of the members of the household. These decisions are made according to the particular structure of opportunities in each city, the timing of the economic cycle, and the life cycle of

the household (Grasmuck & Pessar 1991; Massey et al. 1987; Selby & Murphy 1982).

To consider households as a resource-pooling unit is not denying the power and interest differentials that exist along gender and age lines within the household. Household strategies are sometimes the result of consensual decisions, but often are imposed by some household members against the opinions of other individuals within the household. Households encompass ties of solidarity and affection, as well as points of tension and conflict (Beneria 1992; Safa & Antrobus 1992). At all events, households are important decision-making units. This work makes abstraction of intrahousehold conflicts and focuses on household economic strategies and their responses to remittances.

The main claim of this article is that remittances are a rational and important strategy for subsistence and mobility under deteriorating labor market conditions. In order to examine this claim, this study analyses three topics that are central to an understanding of the relationship between remittances and household dynamics in the new labor market conditions:

(1) What are the main characteristics of the households that receive remittances? Previous research has found that those households that could afford sending members abroad in order to receive remittances were the better off among the low-income sector households (Grasmuck & Pessar 1990; Selby & Murphy 1992). We claim that the economic crisis of the 1980s caused an expansion of the migration-remittances strategy to include the lower socioeconomic strata.

(2) What is the importance of remittances for household income? How important are remittances compared to other determinants of household income, such as the income of the head of the household or the presence a secondary income? Previous research has emphasized the importance of remittance income for low-income households (Funkhauser 1992; Massey et al. 1987; Selby & Murphy 1982). We claim that in the context of the new export-oriented development policies, remittances have become a fundamental source of income for lifting households out of poverty.

(3) What is the effect of remittances on the labor force participation of the head and other members of the household? Selby and Murphy (1982) found that in Mexico in the late 1970s, migrant-sender households sent more people into the labor force than nonsender households. Funkhauser (1992), on the other hand, found that during the 1980s, remittances allowed people to withdraw from the labor market in El Salvador, thereby relieving unemployment pressures. We claim that in the context of deteriorating labor markets, remittances allow households to send fewer people into the labor force, and thereby help reduce unemployment and underemployment.

The examination of these questions is important in order to understand why households in peripheral cities take upon themselves the cost and the strain of sending members abroad. This study also may contribute to understanding why migration persists in spite of an increasingly hostile reception in the core countries.

Data and Method

The data for this study were gathered in a survey conducted in four capital cities of the Caribbean Basin in the fall of 1991. This area was selected for the present study because during the previous decades it has been a major "labor export" area. The debt crisis and policies of structural adjustment enacted during the 1980s only served to increase the migration flows from the area (Portes & Grosfoguel 1994; Sassen 1988). The countries selected for the study were Jamaica, the Dominican Republic, Haiti, and Guatemala.[1] The four share a number of characteristics. First, they are all small countries with a high concentration of their population in the capital city. The four are beneficiaries of the Caribbean Basin Initiative, and their economies are highly dependent on the exports of a few commodities, mainly to the U.S. market.

The economic crisis of the 1980s brought about a shift in development policies. In order to balance their trade deficits and meet their debt obligations, the Latin American and Caribbean countries switched from an inward-oriented development strategy towards an export-oriented one, and implemented World Bank-inspired structural adjustment policies. These policies entailed an abrupt opening of formerly protected economies and their exposure to world market pressures, as well as the reduction of state intervention in the economy — i.e., a reduction of the fiscal deficit, trade and financial deregulation, as well as extensive privatization (Beneria 1992; Ghai & Hewitt de Alcantara 1990; Portes, Itzigsohn & Dore 1994).

The new export-oriented policies have had strong effects on urban labor markets. Formal employment in large firms decreased, public employment diminished, and public sector wages deteriorated. Open unemployment rose to high levels. Fewer jobs were created, and the new jobs were of a lesser quality than those created in the previous period (PREALC 1987). The countries of the region attempted to take advantage of the windows of opportunity opened by the Caribbean Basin Initiative, which prompted a rapid growth in assembly manufacturing in export processing zones (EPZ) or in "maquila" firms.[2] These industries, however, are based on the comparative advantage offered by the low cost of labor.

Table 1 shows both the depth of the crisis the area suffered during the 1980s and the importance that workers' remittances had on the economies of these countries. Guatemala and the Dominican Republic experienced a decline of GNP per capita throughout the decade. Jamaica underwent a recuperation and growth of GNP per capita in the second half of the 1980s, but had suffered a severe reduction during the first half. In Haiti, this indicator grew consistently, but it is still the lowest in the entire hemisphere, less than half that of the Dominican Republic. The table also shows the growing importance of workers' remittances as a source of foreign exchange. The size of remittances as a proportion of the export of goods and services has grown during the 1980s. In Jamaica and the Dominican Republic, this proportion declined toward the end of the decade, but is still higher than at the beginning of the decade.[3]

The four countries display differences in their levels of economic development and in their political system. They include the poorest nation of the hemisphere (Haiti), one of the most industrialized countries in Central America

TABLE 1: Evolution of GNP Per Capita and Remittances during the 1980s[a]

(Guatemala), and the country that has developed the largest EPZs in the region (the Dominican Republic). Politically they vary, including a stable democratic parliamentary system (Jamaica), a presidential democracy (the Dominican Republic), a fragile emerging democratic regime (Haiti), and an unstable democracy plagued by civil war and human rights violations (Guatemala). These political and economic differences are important to the comparative aspect of this study. Common findings registered in different settings indicate a more general trend than those observed in similar contexts. At the same time, if we find differences in the relationship between remittances and household strategies in the different cities, we can attribute these differences to the different characteristics of the countries (Przeworski & Teune 1970). The countries vary also in their migration history. A brief description of migration from each of the four countries is necessary to understand how differences between the migration processes from each country may affect household strategies in each city.

The destination of the Dominican migrants is mainly the U.S. This migration began after the invasion of the Dominican Republic by U.S. troops in 1965, initiated as a way to alleviate social and political pressures on the island. Until the 1980s, migrants were mainly from urban lower-middle-class origins. During the 1980s, due to the worsening of economic conditions on the island and the presence of a Dominican community in the U.S., migration is reported to encompass all social strata, from urban poor to professionals (Grasmuck & Pessar 1991; Guarnizo 1992).

Until the 1980s there were two types of migration from Haiti: first, there was the migration of laborers to the sugar cane fields of the Dominican Republic or the Bahamas; second, there was a migration of middle-class political refugees to Canada, France, and the U.S. During the 1980s, the economic crisis and the presence of a community of migrants in the U.S. prompted large numbers of impoverished Haitians to set sail on precarious boats in an attempt to reach Florida (Portes & Grosfoguel 1994).

Jamaican migration until the 1960s was directed mostly toward Great Britain. In the 1960s the British government erected barriers against migration from the Commonwealth countries, while labor recruiters began to bring workers from the West Indies to the sugar plantations of Florida. These two developments caused the tide of Jamaican migration to turn to the U.S. At the same time, Jamaican professionals also received incentives to migrate to the U.S. (Portes & Grosfoguel 1994).

Guatemala before the 1980s was not a labor-exporting country. During the 1980s, however, two important migration movements took place. First, civil war triggered a large migration from the rural areas to southern Mexico and Belize. Second, there was an economically motivated migration of urban origin headed for the U.S. (Hamilton & Stoltz Chinchilla 1991), a migration that is reflected in this study.

Data collection for this study was conducted by local research teams directed by senior social scientists. Budgetary limitations prevented the organization of city-wide representative surveys. Instead, the local teams designed a two-stage survey with a view to capturing the characteristics of the "popular" sectors in each city. In the first stage, the local research team selected a number of neighborhoods in each city[4] in an attempt to capture the variety of middle-low-income and low-income groups. The areas ranged from those inhabited mainly by public employees and formal manufacturing workers to shantytowns inhabited mainly by informal workers. In stage two, stage households were selected randomly within each neighborhood. In each household the head was interviewed.[5] Thus, the results of the survey cannot be generalized to the whole population of the city. Nevertheless, the findings provide important evidence concerning the economic behavior of middle-low-income and low-income sectors households.

In Santo Domingo and in Guatemala City, the research teams conducted 400 interviews. The survey encompassed four neighborhoods in the former city, and three in the latter. In Kingston, the sample comprised 800 cases due to the attempt to cover both the low-income population of the city itself and the adjacent suburbs. In Port-au-Prince, a survey of three neighborhoods was carried out. The plan was to sample 400 cases, but the military coup that ousted

President Aristide made completion of the survey impossible. The researchers, however, managed to complete 300 interviews, most of them before the coup.

The same questionnaire was applied in each city to insure comparability of results.[6] The questionnaire included items on demographic and socioeconomic issues such as marital and migratory status, number of children, education, occupation, income, members of the household in the economically active population, and ownership of the house. It also included questions about migrant relatives, their whereabouts, whether they send remittances or not, and the monthly amount sent. This information elucidates the economic strategies of the households in the cities included in this study.

Although the data used in this article are cross-sectional, they help us to understand the process of change that affected the Caribbean Basin during the 1980s. As shown in Table 1, the importance of remittances has greatly increased during the 1980s in all the countries included in this study. A comparative analysis of the effects of remittances on middle-low-income and low-income households in the context of deteriorating labor markets can provide an explanation for the trends shown in Table 1. Comparison with previous research will provide additional strength to our conclusions.

Characteristics of Households Receiving Remittances

How extensive are migration and remittances among middle-low-income and low-income households in the four cities? The survey asked whether the respondent has relatives abroad, the relationship of the relatives abroad to the head of the household, and the location of those relatives. The survey also asked whether the household receives help from relatives or friends abroad, and the monthly amount of this aid. The survey did not ask, however, who among those relatives sends remittances nor the country of origin of these remittances. Table 2 presents general findings about the importance of migration and remittances to our sample.

The first row of Table 2 shows that in each of the four cities, over half of the households have relatives abroad. Haiti and the Dominican Republic are the two countries where middle-low-income and low-income urban migration seem to be most pervasive. The second and third rows show that a large proportion of the relatives abroad are close relatives and that most of the migration households have relatives in the U.S. The last row shows that the households that receive remittances constitute a considerable portion of the households with relatives abroad. Guatemala exhibits the lowest proportion of households with remittances, but as mentioned above, urban migration from Guatemala is a relatively new phenomenon.

Table 3 presents the main demographic characteristics of households that receive remittances. The first two variables — gender and age — are individual characteristics of the head of household. These two variables indicate that women and older heads of household receive remittances more than other heads of household. However, these characteristics are significant only in Jamaica and Guatemala. In the Dominican Republic, only age is a significant variable, and in Haiti none of those characteristics is significant.

TABLE 2: Migration Characteristics of the Sample in the Four Cities

	Percentages			
	Jamaica	Haiti	Dominican Republic	Guatemala
Households with relatives abroad	59.3	69.0	76.7	54.7
Households with direct relatives abroad[a]	48.4	21.7[b]	53.6	36.8
Households with relatives in the U.S.	48.7	61.3	67.7	51.3
Households that receive remittances	19.4	40.3	26.8	14.5
Total	792	300	403	400

[a] Direct relatives are parents, sons and daughters, brothers and sisters, and spouse.
[b] In the case of Haiti, the low number of direct relatives may be due to the fact that brothers and sisters were not coded separately but were subsumed under the category "other relatives." Thus, they could not be identified and included in this category.

The next three variables describe the family characteristics of households that receive remittances. The first one is the marital status of the head, which is coded in the following way: married people or people living in consensual unions are grouped in one category, and the rest — people who are single, separated, or divorced — are grouped in another category. This variable is not significant for any of the countries. The next variable — family type — tries to pinpoint the stage of the family cycle of the household. For the purpose of this analysis, the family cycle is divided into four stages. The first comprises recently formed families without children. The second stage consists of families with children too young to be in the labor force. The third stage includes those families in which the older child has reached an age at which he/she can participate in the labor force. The last stage is one in which all the offspring have reached an age in which they can join the labor market. This variable was operationalized in the following way: families without children were considered in the formative stage of the family.[7] Children younger than 15 were considered too young to join the labor force (but that does not mean that they do not in fact join). Offspring above this age were considered old enough to join the labor force. This variable is significant in Jamaica, Guatemala, and Haiti. In the three cases, families in the later stage of the cycle receive remittances more than families in the previous stages. The last of the family variables is the number of children. This variable shows that larger families receive remittances more than other families, but this variable is significant only in the Dominican Republic and Guatemala.

Thus, the family variables suggest that families in a late stage of the family cycle or families with a large number of children have wider access to remittances as a mechanism for their subsistence. These results suggest that as the children of these families grow up, instead of looking for a job in their own city, they migrate and support their families with remittances. The results also suggest that larger families are more able to afford the economic or emotional costs of sending members abroad. The latter coincides with Funkhauser's (1992) findings for El Salvador. Thus the demographic profile of the households that receive remittances is one of female-headed, older households in a late stage of the family cycle, or households with a large number of children.

In order to find the main socioeconomic predictors of remittances, we ran a logistic regression on remittance-receiving households. Households that receive remittances are coded 1, and the rest are coded 0. The independent variables include the demographic variables used in the bivariate analysis in Table 3, in addition to years of education and income. The data on income suffer from a large number of missing values — close to 30% of the sample in the cases of Jamaica and Haiti. In order to solve this problem, we ran an ordinary least squares (OLS) regression on income, including as independent variables gender, age, education, number of children, and type of occupation. Using the coefficients obtained in this regression, we calculated the predicted income for the missing cases.[8]

Our claim is that during the 1980s, as a result of the deep economic crisis, migration, and hence remittances, encompassed all the urban social strata. Therefore, we expect to find that neither of the socioeconomic variables is significant in predicting remittances. The results of the logistic regression appear in Table 4 below and show that the relationship between socioeconomic status and access to remittances differ between the different countries.

Only the case of the Dominican Republic corresponds to our expectations. In this case, education is not significant, while income has a significant but negative effect on the likelihood of a household to receive remittances, suggesting that the poorer households are those that depend on remittances for their subsistence. These findings correspond with earlier reports of the wide socioeconomic scope of the Dominican migration (Guarnizo 1992). The cases of Jamaica and Haiti show a different pattern. In both cases education has a positive and significant effect on the likelihood of households to receive remittances, while income is not significant. These findings suggest that those households with higher human capital are more likely to receive remittances. These results are puzzling since migration from these two countries, as shown in Table 2, is very large. Finally, the case of Guatemala also contradicts our expectations. In this case, income has a significant positive effect, while education is insignificant. These findings may be related to the newness of Guatemalan urban migration.

The work of Massey and his collaborators (1987) suggest an explanation for the variations found in these results. They found that rural households receive larger amounts of remittances than urban households, a finding that they attribute to the different types of jobs that urban and rural migrants sought. Urban migrants found employment in cities where the cost of living is expensive, hence they could not save much to send home.

In a similar vein, the wide access to remittances in the Dominican Republic may be explained by the presence of a Dominican ethnic economy in New York, which offers employment to Dominican migrants. This ethnic economy, as shown by Portes and Guarnizo (1991), is tightly related to the country of origin. Relatively large amounts of capital and goods flow between New York City and the island. The results in the cases of Haiti and Jamaica suggest that only migrants with higher levels of human capital are able to secure incomes that allow them to send money home. Migrants with lower levels of education may engage in recurrent migration that allows them to save some money and return home, as is the case of Jamaican cane cutters in Florida, or in activities that provide merely a subsistence income, as is the case with Haitian cane cutters in the Dominican Republic. The Guatemalan migration flows are newer. In the beginning of a migration flow, the migrants are those who can afford the trip and have the human capital to insert themselves into the receiving society. Social networks in the receiving countries that allow people from all social strata to migrate may not be present yet for Guatemalans.

Remittances and Household Income

In examining the importance remittances have on household income, we claim that in the context of the switch to an export-oriented model of development, based on the comparative advantage of cheap labor, remittances become a central component in the household efforts to subsist or improve its situation. Hence, we expect remittances to constitute an important part of total household income, and we expect households that receive remittances to have a higher total income than those that do not.

For the purpose of this analysis we constructed a variable, "total household income," composed of the sum of the different household incomes — the income of the head of the household, secondary income,[9] and remittances. Cases with missing values in their reported remittances or secondary income were coded as having a zero income in these accounts. This mode of calculation of the total household income is bound to increase the importance of the income of the head of the household vis-à-vis remittances or secondary incomes. This is so because we calculated income values for the missing cases of the former variable. This conservative way of calculating the importance of remittances increases the confidence in our results, which are presented in Table 5.

In Table 5, we should note the very low mean income of the heads of household in the four cities. Paradoxically, the Haitian sample has the highest mean monthly income, though even in this case the mean income is rather low.[10] In the four cases the results support our expectations concerning the importance that remittances have on household well-being. In the four cases, remittances are an important component of total household income; from about one fourth in Haiti to nearly 40% in the Dominican Republic. Moreover, the total income of households that receive remittances is considerably higher than the total income of households that do not receive remittances. These results demonstrate that in a context of deteriorating labor markets, those low-income households that have access to remittances can do considerably better than those that do not.

The results of a comparison of the mean income of the heads of the household in the four cities, correspond with our findings in the previous section, with the sole exception of Haiti. In the Dominican Republic, the mean income of the heads of household that do not receive remittances is higher than that of those households that receive remittances, showing again that in this country the poorest among the urban poor are those that depend on remittances. These results coincide with those of Massey and his collaborators (1987), who found that in the Mexican urban communities the households that relied on remittances were those with the lowest income and the worst labor market prospects.

In Guatemala and Haiti, the situation is reversed: the better off among the poor are those that receive remittances. Table 4 above has already shown that this was the case for Guatemala. In Haiti, education seems to be a better predictor of a household receiving remittances, but Table 5 shows that there are also differences in income. In the case of Jamaica, the mean incomes of both types of household are almost equal. *T* tests conducted on these means were significant in the cases of the Dominican Republic, Guatemala, and Haiti, and

TABLE 5: Means of Different Household Incomes by Remittances[a]

Jamaica

	Household Receives Remittances Yes	Percent	Household Receives Remittances No	Percent
Total income	254.9	100.0	165.9	100.0

[a] Monthly income in 1991 US$

not significant in the case of Jamaica, showing that for the latter case, the mean income of the two types of household is essentially equal.

Remittances and Labor Force Participation

In this section, I examine the effects of remittances on the labor force participation of the head and other members of the household. Our claim is that in the context of high rates of unemployment and underemployment, remittances allow households to send fewer people into the labor force, thereby reducing unemployment and underemployment pressures that are very high in these countries. Remittances also allow people to avoid engaging in the least desirable jobs; these are the trends in El Salvador (Funkhauser 1992).

Table 6 reveals the proportion of heads of household in different occupational categories that receive remittances. The occupational categories used in this article are the following: self-employed, owners, formal workers, informal workers, and people who do not have a regular job. The table shows that households in every occupational category receive remittances. In three of the

countries, however, the largest group is in the "not working" category.[11] These differences are statistically significant in the cases of Santo Domingo and Kingston. These results are consistent with our claim. In Haiti, the exceptional case, owners are the group with the largest access to remittances. Nevertheless, there is also a sizable group of remittance-receiving households in the "not working" category in Haiti.

Table 7 tests the hypothesis concerning the effects of remittances on the employment of the head of household. The table presents the results of a logistic regression on the labor force participation of the household heads. To construct this dependent variable, we dichotomized the occupations variable. People in the category "not working" were coded 1, and the rest were coded 0. In this analysis we used a dichotomous variable to test the effects of remittances; households that receive remittances were coded 1, the rest were coded 0. Additional independent variables include gender, age, education, the number of relatives abroad,[12] the presence of a secondary income, and the number of people in the household who work in addition to the head of the household.

[a] Self-employed are people who conduct their own business without employing anyone else. Owners have their own business and employ others. Informal workers are wage workers not covered by social security. Formal workers are wage workers covered by social security. Not working includes the following categories: unemployed, living from a rent, living from a pension, housewives, students, and other.

The results of the logistic regression show that gender, age, and remittances are the three main predictors of nonparticipation in the labor force. Women and older people, as could be expected, are more likely to be in this situation. In Kingston, Port-au-Prince, and Santo Domingo, remittances have a significant positive effect on nonparticipation. In Guatemala, the effect of remittances is in the same direction, but is not statistically significant. In a cross-sectional study such as this one, it is difficult to infer causality, but the results show a clear negative relationship between receipt of remittances and the labor force participation of the head of household.

A proper interpretation of these findings needs to take into account the labor market context in which this study took place. It is difficult to overestimate the social costs of the changes that have occurred during the last decade. The burdens that the economic crisis and subsequent policy changes have imposed on households are numerous, and have been aptly described elsewhere (Beneria & Feldman 1992). Here we provide some statistics that highlight the labor market situation in these cities. In 1989, open unemployment in Guatemala City was 6.2%, while 33.0% of the labor force was engaged in informal activities. In the same year in Kingston, 11.4% of the men in the work force and 21.8% of the women were unemployed, while 26.0% of the labor force was in the informal sector. In 1991, 26.8% of the urban labor force was unemployed in the

* $p < .05$ *** $p < .01$

cities of the Dominican Republic. Another 25.2% was self-employed. The numbers for Haiti are scarce and unreliable, but it is well known that most of the Haitian economy is informal (Portes et al. 1994). In addition, it is helpful to remember that the means of total monthly income for the four cities are as follow: US$235.9 in Santo Domingo, US$189.1 in Guatemala City, US$183.3 in Kingston, and US$391.0 in Port-au-Prince.

In the labor markets of the cities in the periphery, the notion of unemployment is not equivalent to that of the cities in the core. In places where there is no safety net for unemployed people, most of the people who claim not to work are engaged in some sort of gainful activity, encompassing such diverse ventures as sewing and cooking for the neighbors, organizing rotating saving groups, working day-labor on occasional construction or repair jobs, or selling clandestine lottery tickets (Itzigsohn 1994).

Our results are consistent with the hypothesis that in a labor market situation where the number of well-paid stable jobs is being reduced, remittan-

ces allow heads of household to avoid unwanted jobs. This in turn frees them to engage in all sorts of casual labor that may provide a similar or better income, albeit less secure, than low-paying jobs in the public sector or export assembly manufacturing. In addition, these activities permit more flexible work schedules and sometimes provide the gratification of working independently. This in turn relieves unemployment pressures. The exceptional case of Guatemala, where remittances do not have a significant effect, supports this interpretation. As we saw above, people with a higher income in Guatemala are those who have access to remittances. They have a better labor market position, and so they are not led out of the labor force by remittances. Finally, we are interested in testing the effects of remittances on the labor force participation of additional members of the household. Our claim is, again, that remittances reduce the pressures on the household to insert additional members into the labor market. To test this claim we ran an OLS regression on the number of people in the household who participate in the labor force in addition to the head. The regression includes the individual and household variables included thus far, plus two new variables: the natural logarithm of the income of the head, and a series of dummy variables representing the different types of occupation.[13]

Table 8 presents the standardized results of the regression. In Santo Domingo and Guatemala, the results conform to our expectations. Remittances have a negative and statistically significant effect on the number of people who contribute to the income of the household. In Kingston the effect is in the expected direction, but it is not statistically significant. Only in Port-au-Prince does this variable have a positive coefficient, but not a statistically significant one.

Port-au-Prince is the exceptional case. As shown in Table 6, a large proportion of owners receive remittances in that city. This fact suggests that remittances may be used as a source of capital accumulation by the more financially secure households.[14] These, however, are informal owners who tend to employ family members in their business as a form of primitive capital accumulation — hence the positive sign of the effect of remittances on the labor force participation of household members.

Overall, these results suggest that in most cases, households that receive remittances need to send fewer additional members abroad than those that do not receive remittances. Again, this is important because of the same reasons mentioned above regarding the heads of household. In addition this may allow younger members of the household to stay in school and complete their studies.

In order to test this hypothesis we ran an OLS regression on the ratio of school-age offspring who are in school to the total number of school-age offspring in the household.[15] The independent variables include the independent and the dependent variables used in the previous analysis. The results are not presented because the effects of remittances are not significant in any of the cases.[16] Nevertheless, it is interesting to report the direction of the effects. Remittances have a positive impact on children's remaining in school in Santo Domingo and Kingston, and a negative effect in Guatemala and Port-au-Prince. The negative effect in Port-au-Prince is not surprising given the positive effect of remittances on the number of members of the household in the labor force.

* $p < .05$ ** $p < .01$

The negative effect in Guatemala is more difficult to explain. Santo Domingo and Kingston, however, are the two cities where the lower-income groups have a wider access to remittances. These results, while far from conclusive, provide some support to the hypothesis that remittances help the weakest groups to accumulate human capital.

Conclusions

At the beginning of this article we observed the increasing importance of remittances to the economies of the countries of the Caribbean Basin. Our findings show the social effects of that economic phenomenon. In each of the cities of the study, a large number of households depend on remittances for subsistence or mobility. Remittances are not only an important macroeconomic factor, helping to ease the pressures on the current account, but also they affect the lives of a large number of middle-low-income and low-income people. We also found that, against our expectations, only in the Dominican Republic do remittances reach equally every socioeconomic stratum. In the other three countries, groups with higher income and/or human capital have wider access to remittances. We explain these findings by relating the scope of the availabili-

ty of remittances to the employment opportunities of the migrants rather than to the extent of migration.

As we expected, remittances are a very important component of household income in these social sectors. Households that receive remittances have a higher average income than households that do not receive remittances in the four cities. Remittances thus, are central to the well-being of middle-low and low-income households. We also found that in Santo Domingo, Kingston, and Port-au Prince, remittances allow people to stay out of the labor force. Also in Santo Domingo, Kingston, and Guatemala City, remittances allow households to send fewer people into the labor force. We infer that these effects alleviate unemployment pressures in labor markets characterized by high rates of unemployment and underemployment. Moreover, remittances allow the people in the weakest labor market positions to avoid the worst menial jobs and engage in more flexible forms of employment.

The patterns we found are not similar in every city. We have attempted to explain the divergences. Overall, however, our findings provide support to our claim that in the labor market context of the beginning of the 1990s, remittances constituted a central strategy for the subsistence of low-income households in the Caribbean Basin. Sending members abroad in order to receive remittances is a rational choice of people confronting very difficult circumstances. Those labor market conditions have not changed since then, neither are they likely to change as long as these countries compete for scarce capital through the cheapening of their labor costs.

The main implication of these findings is that an increasing number of households, willingly or reluctantly, are going to send members abroad so that the latter can send back remittances. The most likely destination has been, and will continue to be, the U.S. As large Caribbean migrant communities grow in this country, they provide social networks that facilitate a continuing flow of migrants, in spite of the increasingly hostile attitude of large segments of the U.S. public.

By the end of the 1970s, the import substitution industrialization model implemented in the area since the 1950s was indeed exhausted, and a new form of entry into the world economy was needed. The new direction adopted by the countries of the region was a restructuring of their economies with a new emphasis on export-oriented activities, the bulk of them directed toward the U.S. The Caribbean Basin Initiative (CBI) played an important role in easing the entry of Caribbean exports into American markets. This new mode of entry into the world economy may, in some cases, alleviate the burden on the current account of peripheral countries. It does not, however, increase employment or income. As the societies and the economies of the region become increasingly integrated, it is in the interest of the Caribbean countries, as well as the U.S. — the main recipient of the migration flows — to make a joint effort to find better means of economic integration, to find a development strategy based on the development of the human capital of the region and on dynamic, rather than static, comparative advantages.

Notes

1. San Jose, the capital of Costa Rica, was also part of the study, but due to the low importance of migration from Costa Rica, it is not included in this article.

2. In this work, the term *maquila* refers to firms that, although not located in export zones, receive the benefits granted to the latter in terms of facilities for import and export assembly manufacturing products. This is important to note because sometimes the term *maquila* is used to refer to any firm that does subcontracting work for others.

3. This decline is probably the result of the growth of exports as a result of the export-oriented development policies.

4. In Jamaica, where updated statistical information is available, the selection of neighborhoods was made according to measurable criteria. In the other three countries the selection was conducted according to whatever statistical information was available, in addition to the knowledge of the city of the research teams, which have been conducting research in their countries for long years. Post-hoc tests of the characteristics of the sample in the different neighborhoods confirmed that the choices correspond with the researchers' assumptions.

5. The respondents had to be 30 years of age or older. This is so because the survey attempted to capture the changes in the economic position and the perceptions of the respondents as a result of the crisis of the 1980s.

6. The original questionnaire was written in Spanish, and translated by the research teams into English (Jamaica) and Haitian Creole.

7. Single people without children are included also in this category. The reason for this is their small number in the sample.

8. I prefer this method to others, such as assigning the mean value to the missing cases, because in this case the predicted income is related to the characteristics of the individuals and the sample. In order to check that no major distortion of the data was caused by this method of calculation, I ran a series of t tests comparing mean incomes of different groups. For this I used the new variable that includes all the cases and the original variable, which included only the cases that reported income. I compared the means for gender, occupation, and whether the household receives remittances. The results of these tests show that in all cases the means of the new variable are slightly higher than the original ones, but they reproduce the same patterns for the different groups as the original ones. These results are available upon request from the author, and they suggest that the new income variable can be used with confidence.

9. Secondary income refers to contributions to the household income earned locally by people other than the head of the household.

10. We think this result is paradoxical since Haiti is the poorest country of the four included in this study. This could be the result of the presence of outlier cases in the sample, or of a high exchange rate for the local currency at the time of the survey (incomes were reported in local currencies and transformed into US$ using the official exchange rate of the time of the survey).

11. The category "not working" is a broad one. It includes people that are actually searching for a job and people that are outside of the economically active population (e.g., housewives, people living off a pension or other sources of income not related to current employment).

12. The number of relatives abroad is a continuous variable, ranging from zero for households without relatives abroad, to three for households with three or more relatives abroad. The limit of three is due to the fact that the questionnaire did not ask about the total number of relatives abroad, but about the relationship and whereabouts of the closest three relatives of the respondent who reside abroad.

13. The effects of the dummy variables are not absolute effects, but should be compared to a reference category that is omitted from the regression. In this case, the omitted reference category is formal workers.

14. This interpretation coincides with the findings of Portes and Guarnizo (1991) for the Dominican Republic and Massey et al. (1987) for Mexico.

15. School-age offspring are those older than 5 and younger than 19.

16. These results are available upon request.

Why Do Daughters Leave School in Southern Africa? Family Economy and Mothers' Commitments*

BRUCE FULLER, *Harvard University*
JUDITH D. SINGER, *Harvard University*
MARGARET KEILEY, *Harvard University*

Abstract

By focusing on the family economy and its capacity to mediate broad economic developments, sociologists are beginning to move beneath macrostructural forces to better explain parental demand for schooling and children's attainment. This materialist model focuses on the explanatory power of contextual labor demand and resources internal to the family. Parents' social preferences and commitments, antecedent to "choosing" between work or school for their children, are presumed to covary with economic factors. In contrast, research on family practices within impoverished settings reveals that parents' social commitments linked to child development or schooling can vary independently of the family's economic circumstances. Applying these alternative theories to family behavior in southern African, we assess the relative influence of mothers' economic demands and social commitments on their daughter's probability of staying in school. We find that the risk of daughters leaving school is more strongly influenced by mothers' social commitments than by household economics. Maternal influences do interact with selected family-economy indicators and are conditioned by the level of discretionary time afforded to daughters.

Children around the world, and within particular societies, leave school at widely varying ages. Efforts to identify the underlying causes of why, and when, children are likely to exit school have greatly influenced two competing

* *David Cownie and Elizabeth Blake assisted enormously in the design and implementation of this study. models of social action and attainment. Individual-level *rational choice* theorists posit that parents actively construct strategies for maximizing the family's economic returns, investing in their children's human capital within the household's budget constraint (Becker 1976; Coleman 1986; Schultz 1961). In contrast, *macrostructural* proponents argue that national or local opportunity structures — reproduced through dominant forms of status attainment, labor demand, social-class membership, or state-constructed supply of schooling — determine how far children go in school (Garnier, Hage & Fuller 1989; Hauser & Daymont 1977; Ogbu 1978; Rubinson 1986).

Recently the *family economy* has received attention from social historians and sociologists — as an intermediary organization that actively accommodates novel labor demands arising within industrializing economies (Hareven 1982; Horan & Hargis 1991; Robinson 1993; Walters & O'Connell 1988). This new conception of family economy — and its capacity to explain change in the allocation of children's time between school and work — draws on the household economist's basic model: parents intentionally advance their child's interests, mediating labor demands and seeking income benefits found within a modernizing environment. This model, however, also draws on institution-level work, emphasizing that the range of strategies available to the family is bounded by dominant forms of production, labor demand, and political organization that comprise the opportunity structure (Carnoy & Levin 1985; Walters & James 1992).

Research on school attainment within impoverished settings takes a different tack, emphasizing that family strategies and parents *social commitments* are further constrained by forces that vary among households within a particular social class. Among low-income parents, for instance, time spent supervising children's schoolwork in the U.S. (Astone & McLanahan 1991) and parental endorsement of the school itself, cross-culturally, can vary significantly (Goodnow & Collins 1990). This alternative framework suggests that parents' social commitments are influenced by economic demands; yet their acquired beliefs may operate somewhat independently. When the family's institutional commitments do vary independently of economic position, neither deterministic macrostructural nor intention-filled family-economy explanations of attainment are complete.

Our study of daughters' educational attainment in southern Africa advances this debate over how to explain family demand for schooling by (1) assessing the independent effects of economic demand *and* social commitments held by parents, (2) isolating parental beliefs that are specific to schooling and literacy, rather than seeing parental values and preferences as psychological phenomena uncoupled from particular institutions, and (3) focusing on how mothers' economic resources, gender-specific labor demands, and social beliefs help to explain their daughter's attainment. We first discuss how the family-economy framework can be broadened. We then apply this more complete, and gender-specific, model to the commercializing society of Botswana.

Family Economy and Parental Commitments

MATERIALIST EXPLANATIONS OF FAMILY DEMAND FOR SCHOOLING

The family-economy model, as it evolves to explain school attainment levels, has made four distinct conceptual advances: (1) in contrast to macrostructural explanations of demand for schooling, family-level "choices" and children's resulting enrollment (or work) behavior are directly observed; (2) competing demands placed on the family are observed historically, looking out into a heterogenous environment from parents' own viewpoint, not simply inferring uniform family responses to aggregate labor-demand shifts or action by the state (Walters & James 1992; Walters & O'Connell 1988); (3) departing from the neoclassical household-economics model, parents are viewed as enmeshed in economic interdependencies *and* social obligations, rather than assuming that parental decisions about their child's schooling are made individually for each child in a normative vacuum (Hareven 1982; Tilly & Scott 1978); and (4) the influence of gender-related attributes of the family on attainment has been introduced, including effects of mother's income (e.g., from boarders) and gender composition of the household (Horan & Hargis 1991; Robinson 1993).[1]

The sociological version of family-economy does converge with the earlier household-economics model. Both assume that the structure of production and work is the principal determinant of schooling demand. Walters and O'Connell (1988) point out that human capital theorists have erred by focusing on *long-run* returns to schooling (presumably calculated by parents), as opposed to *immediate* production or income needs faced by the family to which children can contribute. But the argument remains principally a materialist one: parents' demand for schooling flows from short-term income and labor needs, involving their children's contribution to subsistence farm production or to the family's cash earnings. Both versions have recently introduced the supply and quality of the *school institution* as a factor in the formulation of family strategies, linking to actions by the state (Knight & Sabot 1990; Walters 1992). Thus, within modernizing environments the family is seen as mediating economic *and* contested institutional norms about how children should normatively spend time between work and school. The macrostructure is variegated both in terms of diverse local economic conditions and in the range of possible social commitments that may be extracted by parents. It is, therefore, not surprising that individual households vary in how they negotiate these environs (Hernes 1976).

THE FAMILY INSTITUTION'S COMMITMENTS: BROADENING THE FAMILY-ECONOMY MODEL

Our study applies a broader conception of the family-economy model to the issue of school attainment and parental decision making in contemporary Botswana. We briefly outline how the basic model can be extended to include material *and* social factors operating within the household which may influence the child's propensity to stay in school. First, early research on school attainment pointed to the role of the child's social-class membership in predicting how far she or he went in school (Sewell & Hauser 1975). Only recently have survey researchers attempted to uncover *why* social class matters and *how* family

strategies or specific parenting practices differentially influence children's commitment to and performance in school (Astone & McLanahan 1991; Baker & Stevenson 1986). Comparative research reveals that parents' endorsement of the school institution and their enabling behaviors (e.g., time spent helping children with homework) vary significantly among families *within* social class groups (Goodnow & Collins 1990), and parental beliefs directly linked to schooling more consistently predict children's attainment, compared to the earlier focus on parents' general values regarding modernity or individualism (for review, Hess & Holloway 1984).[2]

Second, the family-economy framework emphasizes material demands faced by, and resources available to, parents. The surrounding structure of (subsistence or industrial) production and labor places demands on the family, depending on their position within the occupational structure (Horan & Hargis 1991). The assumption is that work demands placed on children by parents significantly cut into time available for schooling (the influence of opportunity costs and the budget constraint within the neoclassical model, Becker 1976). However, parents' commitments (e.g., endorsement of the school's utility) represent socially constructed "resources" that also may influence school attainment, independent of wealth or macro labor demand. Family structures hosting these social resources are reproduced not only through economic processes but also through institutionalized cultural scripts and commitments (Angel & Tienda 1982; LeVine 1987). While child labor demands can be significant within impoverished communities (historically) or in peasant societies (currently), *discretionary time* made available to children varies widely across local settings.

Family-economy theorists have yet to confront the issue of how the social meaning and behavioral correlates of class position may be conditioned by local culture. The class position of fathers in contemporary Western societies may be related to individual values and child-rearing beliefs (Kohn et al. 1990). But it remains unclear whether typical indicators of class membership (wage-sector occupation, cash income) provide useful predictors of children's school attainment in non-Western societies.[3] How mothers and daughters spend time in the household, and the amount of discretionary time made available for school, may be reinforced by gender-specific cultural scripts that characterize the family institution; but this process may be only loosely coupled with the father's position in the wage economy.

Research on school attainment in developing countries similarly emphasizes household economy factors, especially when focusing on gender inequality. Studies of Third World households show that mothers and daughters may spend twice the time on labor tasks each week, relative to male members (Dixon-Mueller 1985; Hill & King 1993). Hyde's (1993) empirical review, however, pushes further to show that social and institutional factors also influence female attainment in certain settings: local norms regarding marriage and childbearing, religious beliefs linked to literacy, parents' selection of which children are encouraged to stay in school, and quality of the local school (also, for Kenya and Tanzania, see Knight & Sabot 1990; for Ghana, Glewwe 1991).

This leads to the third area: the family-economy framework can be pushed forward to carefully assess gender dynamics within the household. Both

economic and social demands placed on mothers differ from those faced by fathers. And parents' definition of, and strategies for advancing, daughters' status may differ relative to sons'. Where wage-labor demand systematically varies for female versus male graduates, parental decision-making related to school attainment predictably varies based on gender (Horan & Hargis 1991; Rosenzweig & Schultz 1982). In many developing countries, the "social opportunity cost" of staying in school may be high, where postponing marriage beyond age 15 or 16 can have sharply negative consequences for the daughter's and parents' social status. Mothers also may mediate labor and social demands facing their daughters; for instance, initial Third World evidence suggests that girls' school attainment is higher when the mother controls household spending, often within father-absent households (Schultz 1990).[4]

Our empirical study of daughters' school attainment in southern Africa first applies a basic *family-economy* model to contemporary households (equation 1). Then, we study a broader model that focuses on *gender-specific elements* of the family economy (equation 2). Finally, we assess a *family-institution* model which adds social commitments held by the mother which may further explain daughters' school attainment. We turn next to specific conditions found within rural Botswana villages, and then technically specify the three models.

Explaining Daughters' Attainment in Southern Africa

BOTSWANA CONTEXT

Botswana lies immediately to the north of the Republic of South Africa. About 85% of its 1.5 million inhabitants are from the Tswana tribe; a greater number of Tswana people live within South Africa and neighboring Namibia. Botswana has a strong cash economy, relative to other sub-Saharan African countries. Gross national product per capita equalled US$1,050 in 1987, but income inequalities are enormous. Botswana's rapid commercialization stems from rich diamond mines and a sizable beef-export sector. The proximity of wage jobs in South Africa has historically influenced labor migration of males, and thus family structure (Brown 1983). Two-thirds of the labor force still works outside the wage sector, primarily in livestock herding, farming, and the informal cash economy. Given that Botswana's rapid development disproportionately affects urban elites, economic and social practices remain traditional in many rural households. Despite a decline in the fertility rate, for instance, it remains high, with population still growing at 3.4% annually, compared to 2.4% in South Africa (Colclough & McCarthy 1980; World Bank 1991).

Females in Tswana culture have historically attended to domestic obligations: bearing and supervising children, preparing meals, and maintaining the family compound. Women quite frequently brew and sell beer to earn cash, especially in father-absent households (Alverson 1978). Adult and adolescent males have traditionally migrated to towns for cash-earning jobs, worked at the family's cattle post (grazing lands where herds are raised, an area that may be just outside the village or a day's walk), or tended the household's land plot (with female members). Time spent working the land is limited, however, given Botswana's arid climate. This allows children considerable discretionary time, a

crucial condition 'under which parents allocate time between work and schooling.

Government, since independence (1966), has rapidly expanded schooling: primary enrollments have quintupled, now equalling 85% of the age cohort. The number of secondary schools has grown from six to 140. At this level gender inequities arise: girls begin to leave junior secondary school (grades 8-9), many due to pregnancy or marriage. By age 19, 49% of all females are either mothers or experiencing their first pregnancy. By grade 9, boys are outperforming girls in most subjects (Duncan 1989; Kahn 1988).

DATA AND MODELS

In-depth interviews were conducted with 122 mothers, each having a daughter of secondary-school age. Ethnographic work also was conducted in one village, the findings of which are not reported here. A standard interview protocol was used which included forced choice and open-ended questions. Interviews were conducted within the household compound and in the indigenous language (Setswana), each lasting between 105 and 180 minutes. Within each of four villages, we randomly selected mothers of 15 girls who were presently attending junior secondary school; neighboring households were then visited until another 15 mothers were found, each with a school-age daughter who had dropped out of school before completing junior secondary school.[5] Literacy tests also were administered to the mother and "target" daughter.[6]

General Hazard-Rate Model

We analyze the effect of family-level factors on the risk of daughters' leaving school, using discrete-time survival analysis (Singer & Willett 1993; Tuma & Hannan 1984). Let T represent a discrete random variable indicating the grade when a girl exits school. In discrete-time survival analysis, rather than focus on the distribution of T directly, we focus on the distribution of discrete-time hazard, h_i, defined as the conditional probability that a randomly selected girl will drop out of school in grade j, given that she did not drop out of school before grade j:

$$h_j = Pr[T = j \mid T \geq j]$$

Because event occurrence is inherently conditional (a girl can drop out for the first time only if she has not dropped out already), this set of conditional probabilities represents the fundamental parameters of the discrete-time survival process that we study. Details of the model are available from the authors.

Basic Family-Economy Model

To test the basic family-economy model at the household level, predictor variables related to labor demands experienced by family members were included, as well as indicators of the household's material wealth or poverty.[7] We express this simple relationship between family-economic factors and the risk of leaving school as:

$$logit(h_j) = f(G,L,Y) \tag{1}$$

where the risk of leaving school in grade j [h_j] is expressed as a logistic function of grade in school [G], labor demands emanating from the local economy and mediated by parents [L], and income and resources available to the family unit [Y]. Expressed at the household level, this is the basic function advanced in the family-economy literature as reviewed above.

Gender Specific Family-Economy Model

Our second model improves upon this conceptualization by including variation in gender-specific work demands for females, and labor demands relative to males. Also included are culturally relevant measures of family resources that indicate not only aggregate income but also subsistence-level production, livestock holdings, and consumption preferences (separating long-term household investment from the possession of less durable consumer goods). This more complete and locally situated model is specified:

$$logit(h_j) = f(G, Lf, Lf/Lm, Of, Om, Yp, Yc, Yi) \quad (2)$$

where the risk of leaving school is expressed as a logistic function of labor demands placed on daughters within the household [Lf], the number of labor tasks allocated to females minus tasks allocated to males [Lf/Lm], wage-sector employment of the mother [Of] and father, if present for most of the year [Om], and wealth measured by volume of subsistence production [Yp], possession of nondurable consumer goods [Yc], and level of investment in, and quality of, the household compound [Yi]. Descriptions of these indices appear in the Appendix. Model 2 does not depart theoretically from the standard family-economy model; it does directly observe female-specific labor demands and resources that mothers might influence, on which initial Third World studies of attainment have focused (e.g., Hill & King 1993).

Family-Institution Model

The social structure, beliefs, and school-related practices of parents, especially those exercised by mothers, may vary independently of economic variables to further explain daughters' school attainment:

$$logit(h_j) = f(G, HA, AM, Sa, Sed, Med, Fed, Flit, Fread, Sq, Su, Ffert) \quad (3)$$

where the risk of leaving school stems from the number of adults residing full-time in the compound, presumably providing stronger supervision of children [HA], whether the father has left the household permanently or is absent more than two months of the year [AM], age and education level of the target daughter's siblings and father's education level [Sa, Sed, Fed], mother's education, assessed literacy level, and reading practices (i.e., materials and frequency with which the mother reads) [Med, $Mlit$, $Mread$], the quality of the local secondary school and utility of keeping one's daughter in school, as perceived by the mother [Sq, Su], and the mother's fertility practices [$Mfert$], including use of birth control methods and fertility rate, as indicators of attitudes toward child bearing and more individualized socialization of offspring (LeVine 1987).[8]

This third model supplements standard family-economy indicators of social beliefs and practices that may vary independently of the household's economic

status, as shown in the comparative research outlined above. We append the term "institution" in labeling the model since the reproduction of these social beliefs and cultural scripts occurs within the family organization *and* may be externally disrupted by alternative ideologies and scripts introduced by modern institutions (i.e., schools, health clinics, and the media).

As the analysis proceeded, two sets of interaction terms were studied. Household-economy and maternal social factors may interact with the grade level in which the daughter is enrolled, especially since the hazard of dropping out rises at the end of primary school (grade 7) and junior secondary school (grade 9). We also discovered that hazard rates varied depending on whether the family resided in a southern or northern village. So, southern residence was interacted with principal economic and social predictors. For all three models nonlinear forms of the predictors (two-degree polynomial terms) also were assessed.

DESCRIPTIVE FINDINGS

Table 1 summarizes descriptive data, splitting households between those where the target daughter was attending the junior secondary school (*in-school*) versus those where the daughter had left school (*out-of-school*). Just 54% of mothers surveyed were married. Of these households with married couples, 45% of the fathers were no longer full-time residents of the compound: they were living in town, South Africa, or at the cattle-post for two months or more during the year. Mothers with out-of-school daughters were significantly older than mothers with in-school daughters, although no differences were found in the age of the target daughter or in her birth order. On average, four adults and six children lived in the household.

Family Economy

Less than one-third of all mothers were employed in a cash-earning job. Among senior males in the compound (not necessarily the husband), 34% earned cash at least on a part-time basis. Mothers reported performing six domestic tasks alone each day, on average; another four tasks were performed together by the mother and daughter. In contrast, the household's senior male was responsible for one and a half daily tasks and performed one additional task with a household member. The family's involvement with formal markets is highly variable. About one-third took livestock to market, mostly cattle, goats, and chickens. The brewing and sale of traditional beer was a common market activity. About 60% of the households owned an ox-pulled plow, indicating at least subsistence production of sorghum or maize. These latter indicators of *household production* were combined into an index of household production.

Two other measures of household wealth were constructed. An index of *consumer goods* present in the household was developed, including items shown in Table 1. For example, 75% of all families owned a working radio, 34% had a bicycle. The enumerator also made an assessment of *household quality and investment*. Culturally specific items included in this index: presence of a square ("modern") house in the compound in addition to traditional round huts (78% of households), whether the thatch on the roof was of high quality, cut by a

craftsperson in a close-cropped manner (68%), whether only a primitive latrine-pit was apparent (10%), and whether a water standpipe existed within the compound (24%). This index of housing quality proved to be the only economic indicator consistently related to the daughter's probability of leaving school.

Schooling and Mothers' Social Beliefs

Mothers (but not senior males) differed in their level of school attainment (those with daughters in-school, 5.4 years; out-of-school, 3.5 years). Mothers with in-school daughters also performed significantly better on our brief literacy assessment, as did their daughters. Furthermore, two beliefs linked to schooling and fertility behavior were consistently related to daughters' school attainment: how the mother perceived the quality of the local secondary school, and whether the mother used a birth control device. Seven individual scales were used to assess mothers' perception of school quality (see Appendix). Mothers with daughters in school had higher perceptions of quality of the local school than mothers with daughters out of school. Furthermore, reported use of birth control was indeed related to the number of children to whom the mother had given birth. Mothers who used a birth control device had fewer live births (mean equalled 6.1) compared to mothers not using birth control (6.5).

HAZARD-MODEL FINDINGS: WHAT HOUSEHOLD FACTORS EXPLAIN DROP-OUT RATES?

The study of school attainment has been hampered by two analytic problems: variability in key outcomes — whether the child is still attending school and their years of attainment — is heavily dependent upon when the survey is conducted or the time points chosen for the analysis. Right censoring of cases often occurs for many individuals in the sample: the student may drop out the year after the survey is conducted, but this datum is never known. Nor can cross-sectional regression methods (or historical time-series models of school attainment) factor in variability associated with *when* children leave school. By applying hazard or event-history techniques, we can more adequately model the probabilities of *whether* and *when* girls leave school, based on cross-sectional survey data.[9]

Figure 1 plots the baseline hazard rate of leaving school by grade level as a percent of girls still in school relative to the previous year. For our sample, all but one girl stayed in school through grade 6; then 9% of the remaining girls dropped out prior to completing grade 7; and 26% of the remaining girls left school prior to grade 8 (the first year of junior secondary school). Institutional demarcations, particularly the transition from primary to secondary school, make a big difference. Among remaining female students, another 25% dropped out before or after completing grade 9. Substantive predictors are then added to this baseline function; improvements in fit can be evaluated by examining decrements to chi-square statistics.

Family-Economy Effects

The basic family-economy model is moderately efficacious in explaining variation in whether and when girls leave school. Just one of the three measures of household wealth proved to be related to daughters' school attainment: the index of household quality and investment that is added to the baseline hazard-rate function in model B (Table 2). The decrement in the chi-square value is highly significant. The coefficient's negative sign indicates that the probability of dropping out is *lower* among families with higher scores on the household-quality index. The composite measures of household production and ownership of consumer goods show no effect.

Above we saw wide variation in the number of household tasks required of children, and unequal labor demands placed on daughters versus sons. But neither household-labor nor employment-status predictors held significant main effects on daughters' attainment. The level of gender inequality found within southern villages does significantly *raise* the probability of girls' dropping out. This demonstrates the utility of broadening the standard family-economy model to look at gender-specific labor demands. A direct trade-off between time spent in school and working may not exist for most Botswana youths. In general, many children and youths appear to have a good deal of discretionary time, not found in peasant societies that are more dependent upon subsistence agriculture.[10]

Next we turn to the wider set of social factors specified in our *family-institution* model that may independently influence daughters' school attainment or which my interact with family-economy factors. Social and institutional processes are split into two areas: family social structure and mothers' own schooling, literacy, social beliefs, and practices.

Family Social Structure

Two elements of family structure are significantly related to daughters' attainment. First, girls with older siblings generally stay in school longer, as evidenced by the effects from average age of children in the household (Table 3, model B). Daughters with siblings of average age, 11 years, were 3.5 times more likely to still be in school, compared to daughters with siblings of mean age, 5 years. Our qualitative work in one village suggests that this effect is due to more intense child-care responsibilities of daughters who have fewer older siblings (Fuller et al. 1992).

Second, mothers and daughters residing in the two northern villages had significantly *higher* educational attainment — even though these villages had a higher prevalence of absentee fathers. Only 19% of mothers in the North reported that the daughter's father resided in the household, versus 40% among mothers in the South. The family economies looked quite similar, with only sorghum production (for market) higher in the villages in the South than in the North. However, northern mothers had 5.2 years of schooling versus 3.7 years among southern mothers. Daughters had 8.7 years of schooling in the North, compared to 8.4 years among daughters in the South. It may be that labor out-migration is more frequent from the North where proximity to urban labor markets is more distant. This does not necessarily disadvantage the family

economically; women tend to have *higher* school attainment in father-absent households. From at least one other developing country, evidence suggests that mothers support their daughters' nutrition and schooling more equitably when the father is no longer in the household (Schultz 1990). In Botswana, 34.9% of all farming households are headed by women (Botswana Central Statistics Office 1989). Other facets of family structure held no discernible influence on daughters' attainment: family size, number of resident adults, and males' education level.

Literacy Practices, School, and Fertility Beliefs

In contrast to the inconsistent effects of the family economy, several social commitments and practices exercised by the mother were directly related to the daughter's attainment. In Table 3 we report on effects from mother's literacy score, perceived level of school quality, and use of a birth control device. All three social commitments reduce the log likelihood of dropping out when entered sequentially. Girls with mothers who do not use birth control are twice as likely to leave school. Girls whose mothers scored in the highest literacy decile, on average, had entered grade 9, compared to median school attainment of grade 7 for girls whose mothers scored in the lowest decile.[11]

The mother's perceived quality of the local school and the general utility of modern schooling also were associated with a lower probability of dropping out (models C and D). Linear and nonlinear (squared) relationships must be interpreted together (in model D). When we plot the overall hazard function, the effect of mother's literacy on *reducing* the probability of the daughter's dropping out is significant (see Figure 2); the positive effect of mother's school attainment alone is marginal. A similar plot (not shown here) of linear and nonlinear effects of the school's utility shows a significant reduction in the risk of dropping out. The mother's preference for a more obedient (less liberal) daughter *raises* the probability that the daughter will leave school (index detailed in Appendix). Overall, note the substantial reduction in the -2 log likelihood between model A and model D (Table 3) when all social factors are in the equation; this reduction is much less for the family-economy model (Table 2, model C).

Do mothers' social commitments interact with family-economy factors? We tested for effects from three possible interaction terms between the household-investment indicator (wealth) and social-commitment variables. The interaction between investment and mothers' perception of school quality did significantly reduce the chi-square ($p < .01$).

Fully Interactive Grade-Level Models

The next analytic step (1) directly tests the influence of social factors, after controlling for the influence of family-economy factors, and (2) assesses whether economic and social variables interact with school grade levels. The latter procedure provides an assessment of whether the school's own institutional structure interacts with family-level economic and social forces. For example, the end of primary school (grade 7) may be a point at which some parents (with specified economic or social attributes) allow their daughter to leave school.

Where earlier predictors were found to have a significant interaction effect with any *one* grade level on the probability of leaving school, interaction terms between these predictors and *all* grade levels (grade 5-9) were entered.[12] To summarize these findings (the detailed statistical table is available from the authors), first for interactions between specific school grade levels and family-economy factors: the probability of dropping out is higher at the end of grade 7 in households with a greater gender gap in labor tasks. Daughters in the South also have a higher drop-out risk during grades 8 and 9, perhaps when labor demands exerted by the wage economy begin to be felt. Interaction terms for grade levels and maternal social factors are then entered, controlling on the family-economy variables. In addition to already mentioned main effects, the perceived quality of the school holds an effect, particularly during grades 7 and 9. Household quality, mother's literacy, and use of birth control all remain important factors in lowering the drop-out risk, *independent of the daughter's grade level* (i.e., no interaction effects).

In sum, elements of the family-institution model explain additional proportions of variance in daughters' drop-out risk: age structure of the household and implied child-care demands placed on daughters, and particularly, maternal literacy, fertility practices, and child-rearing views (liberal or traditional). The mother's perceptions of schooling may interact with institutional realities in terms of how she perceives the quality of the local school and the utility of formal education in general. And discrete institutional effects are seen in the specific (terminal) grade levels at which the drop-out risk is greatest.

The *magnitude* of selected interaction effects is illustrated in Figure 2. For the family-economy model (Table 2, model C) two interactions have been plotted. First is the interaction of the village's southern location and household quality. The estimated odds of leaving school in any given year are always higher if the assessed quality of the compound is low; but these effects, holding other variables constant, differ depending on whether the compound is in a southern or northern village. In low-quality households in the South, the drop-out risk is over twice as great as in low-quality households in the North. Similar interaction effects are seen in the second economic plot, illustrating the influence of village location and difference in the number of household tasks for which the daughter and son are responsible. In the South, daughters who perform more household tasks than sons are one and a half times as likely to drop out of school than daughters who do fewer household tasks than sons; whereas, in the North, there is little apparent drop-out risk.

For the full family-institution model (Table 3, model D) six predictors are highly related to drop-out risk. Thus the effect of any particular predictor appears to be smaller. Two of the variables have been chosen to illustrate the magnitude of these main effects. The first (Figure 2, bottom left) depicts the effect of mother's literacy score on drop-out risk. In households where the mother has attained a high score on the literacy test, daughters are two and a half times less likely to leave school than daughters whose mothers score low on the test, holding other family-institution factors constant.

(N = 122)

Conclusions

At first glance, our findings might be interpreted as demonstrating the narrowness of the family-economy model, at least when studying female attainment in this African setting. Indeed, *gender-specific* facets of the household economy and family institution — especially maternal commitments related to fertility, child rearing, and schooling — are more influential in explaining daughters' propensity to leave school than more generic facets of family-economy. Our findings, however, do confirm two particular elements of the basic family-economy framework. First, local economic conditions are setting levels of discretionary time available to young females. Just as Walters and O'Connell (1988) found that nineteenth-century rural children in North America had more discretionary time to attend school than urban youths who responded to industrial labor demands, we found sizable amounts of discretionary time. This minimizes the direct trade-off between daughters' work demands and time available for school. Plentiful discretionary time for *mothers* (due to cash remittances from family members) may also condition the variability and attainment effects of maternal social practices.[13]

Second, we find that culturally specific indicators of class position and household resources are related to daughters' attainment levels, especially the family's propensity to save and invest in the quality of their compound. In contrast, neither spending on nondurable consumer goods nor possession of productive assets was related to daughters' attainment. How families accumulate and spend their income may indicate an underlying commitment to longer-term investments. Our findings also lend support to Schultz's (1990) finding that mothers, when they control the allocation of family resources, tend to support their daughters' schooling more equitably relative to that of their sons. We observe this effect in the two most southern villages, where access to jobs in South Africa is closer for husbands. Comparative-historical scholars, data permitting, might pursue this issue of how mothers mediate labor demands and influence the allocation of household resources.

Finally, our findings demonstrate the importance of broadening current conceptions of how the family operates within pluralistic institutional environments, including modernizing contexts that manifest alternative social beliefs and economic options. Maternal commitment to literacy practices at home and their perceptions of higher school quality were strongly related to daughters' achievement, after controlling on family-economy effects. More general beliefs, indicated by endorsement of birth control, also are related to daughters' attainment. This fits with work from Kenya, Mexico, and Nepal showing that more educated mothers individualize their child-rearing practices and explicitly attempt to "develop" their child (LeVine 1987). Precisely how comparative-historical research can get at variation in parents' social commitments, and within what institutional settings these factors interact with family-economy processes, remain intriguing analytic questions.[14] Our analysis also showed interaction effects from terminal grade levels (at the end of primary and junior-secondary school), again evidence of how external institutions blend with household-level forces to influence girls' school attainment.

Proponents of the family-economy framework are pushing us to look into the basic location of action from which parental demand for schooling emanates and variable levels of child attainment result. It moves beyond the assumption that all families respond to the macrostructure in uniform ways; it recognizes that "choices" available to the household are constrained by opportunities set by institutions and markets. By integrating the strengths of this theoretical development with emerging work on parents' social commitments within contemporary settings, we can begin to build a more complete picture of the family organization as situated within a variegated institutional environment. Families, especially during periods of commercialization or symbolic modernization, look outside and confront competing economic demands, social commitments, and parenting practices. In turn, how mothers extract these economic resources and normative convictions from these diverse environs influences how far their daughters go in school.

Notes

1. These conceptual advances are important, particularly in addressing Coleman's (1986) criticism that we often infer local forms of, and motives for, agency from the institutional processes that are deduced from macro theory — but which are rarely observed directly. Avoiding the adoption of an idealized conception of voluntaristic, intention-filled agency, family-economy theory is beginning to demonstrate how the family acts with bounded rationality, given broader institutional constraints and alternative scripts. To illuminate the novel character of the family-economy model, one can contrast it with the status-attainment tradition, focusing on individual attributes of youths (for review, Campbell 1983), and with macrostructural explanations, focusing on historical change in state action, school supply, and institutions (for review, Fuller & Rubinson 1992).

2. Early work on modernization, for example, examined variation among parents in their beliefs and commitment to broad Western values: individualism versus conformity, technical innovation versus traditional farming or work practices (e.g., Inkeles & Smith 1974). Early school-attainment research in the U.S. also examined the influence of parents' expectations and aspirations regarding their child's education (Campbell 1983). But in recent competitive tests between generalized expectations and specific parental strategies (supervision of homework, contacts with school, for instance), the latter proximate causes have been found to be more influential (Astone & McLanahan 1991; Dornbusch et al. 1985). Parental beliefs toward the school's legitimacy and importance can vary somewhat independently of such parenting practices, and may vary within social-class groups (for Japan and the U.S., see Holloway et al. 1990). Variation in cultural or religious commitments to schooling *within* particular social classes also may help to explain interfamily variability in socialization beliefs and parents' push on their children for higher attainment (in the U.S., Alwin 1984; in Africa, Hyde 1993).

3. Initial evidence shows that culturally relevant measures of family social status more consistently predict school achievement, compared to conventional indicators of SES borrowed from Western conceptions of class (for review, Fuller & Clarke 1994). And note that historical research on rural families in the U.S. at times imputes certain social meanings from particular measures of "wealth." For example, higher levels of school attainment among families with more mechanized farming practices are associated with a Calvinist commitment to long-term investment and technological improvement (Guest & Tolnay 1985). But could we make the same inference from economic indicators linked to consumption of nondurable goods or higher levels of farm productivity? Multiple measures of wealth, informed by the culturally specific meaning of each, would reveal more about the consumption preferences of families.

4. Similarly, work in the U.S. shows that adolescent daughters are provided more social opportunities when the mother's class position and influence are more equal to the father's (Hagan, Simpson & Gillis 1987).

APPENDIX: CONSTRUCTED INDICES

Most measures of economic and social variables are discrete and self-explanatory. Construction of several composite indices was done as described below. The interview instrument, available from the authors, was field-tested in two of the four villages.

Economic Indices

A checklist of 27 frequently performed work tasks was utilized, including employment in the wage sector, work on cattle lands or farming outside the household, and domestic tasks inside the family compound. For each task, the mother indicated who normally performed the task: the mother, daughter, husband or senior male, or son. More than one family member could be indicated.

The index of *household production* contained the dichotomous values for crops or livestock most commonly produced for, and taken to, market (see Table 1). Elements of the *consumer goods* and *household quality* indices also are listed in Table 1. Commonly understood criteria were used to distinguish high- versus low-quality thatched roofs and latrines.

To identify culturally relevant work tasks and economic indicators, prior to the field tests we consulted earlier ethnographic research and recent household surveys in Botswana (Alverson 1978; Kossoudji & Mueller 1983; Cownie & Blake 1989).

Social Indices

Mothers' perceptions of *school quality* were recorded by asking nine questions pertaining to the perceived quality of teachers, the school principal's responsiveness to the community, and the quality of the school grounds. Each item used a five-point scale, from "strongly agree" to "strongly disagree."

Four specific questions were utilized to construct the *usefulness of school* index. These items ranged from "Schooling will help my daughter find a wage-earning job" to "Schooling for my daughter will mean she will pass more money to her in-laws and not to me when she gets married" (a frequently mentioned reason for not letting daughters go "too far" in school).

We asked mothers about the behaviors that they like to see in their daughters. Six dichotomous choices were given to the respondent: "Which behavior do you prefer — obeys me *or* learns to speak-up if she disagrees with me?" We constructed the *preference for an obedient daughter* index by simply summing the dichotomous values.

---

5. Each village selected has a junior secondary school within walking distance. Our research team (two interviewers) started at the school, randomly selecting the 15 in-school girls. Each female student was accompanied home. The mother was interviewed; brief literacy tests were given to the mother (orally) and to the daughter (pencil and paper). A bottle was then spun in front of this mother's compound, and we walked in the direction indicated until a mother was found with an eligible out-of-school daughter. This procedure was not intended to yield a random sample: nationwide 65% of all girls in this age cohort are still enrolled in school. Our purposeful sampling technique aimed, first, to provide contrasting subsamples of in-school and out-of-school girls who lived within the same sections of the four villages (Mochudi and Moshupa in the south, close to the capital city and the South African border; Bobonong and

Mmadinare in the north, farther from urban labor markets). The villages were selected primarily for their variable proximity to wage labor markets. Second, we wanted to ensure that distance to school was not the principal explanatory factor. Each village had a junior secondary school close to the village center. We controlled on distance-to-school by first locating a daughter currently attending school, then circling around that household until we located a family with a similarly aged, but out-of-school daughter. All four villages are populated by members of the dominant Tswana ethnic group.

6. Years of school attainment was highly correlated with actual literacy scores ($r = .49, p < .001$). In regressing daughters' literacy scores (based on our 12-item reading comprehension exam) on years of school attained, mother's literacy, and seven additional social and economic household variables, daughter's attainment remained highly significant. The beta coefficient indicated that one year of additional schooling was associated with one additional item correct. The coefficient was five time the standard error. These findings are detailed in an earlier paper (Fuller et al. 1992).

7. Household economists always use individual-level constructs to model school attainment, since they assume that original agency sprouts from this level. Reviewed above, comparative-historical scholars tend to focus on aggregates, for instance, labor demand within a local area or aggregate family income. Studies of family demand or school attainment in contemporary settings often use such contextual measures as well as variables pertaining to individual family members (Horan & Hargis 1991; Rosenzweig & Schultz 1982).

8. Contemporary evidence demonstrates covariation between mother's schooling, the frequency of mother-child interaction, explicit socialization of the individual child (versus more implicit and collective upbringing of the child in the village), and lower fertility rates (for review, LeVine 1987).

9. Studies of enrollment demand in the comparative-historical tradition rely on decennial census or annual survey data. We already know that the influence of contextual economic or political factors on school demand depends upon the time lag used in time-series analyses (Fuller et al. 1992; Walters & Rubinson 1983). As this line of work moves closer to how family characteristics interact with local contexts, time-dependencies linked to whether and when children leave school should receive more specific attention.

10. Tswana settlements traditionally gained cash from cattle for production, which limited labor demands on women and children who remained in the village household. Throughout the nineteenth century, labor migration of males to South African mines and other wage employment helped to raise cash income while making female-headed households very common. In 1971, for instance, there were just 63 young men residing in households for every 100 women in the 20-39 age cohort (Brown 1983). One time-use study in Botswana found that up to 40% of rural adults' time is spent in leisure activities (Kossoudji & Mueller 1983).

11. In 1988, 24% of all young females who had completed some period of secondary schooling, age 15-19, had experienced one pregnancy. This rate of child-bearing was 33% for young females who had not completed primary school (Cownie & Blake 1989).

12. These models become complex. But we have an abundance of degrees-of-freedom, given that the person-period data set, at a minimum, contains over 450 records, one for each person-year of data.

13. Household economists *assume* that parents can vary the amount of time they devote to raising children (Becker, Murphy & Tamura 1990). Note that the Botswana case indicates that discretionary time itself is conditioned by local economic and institutional factors.

14. Historical studies of school demand are taking small steps, for example, beginning to look at the influence of Protestant or Catholic church membership as one indicator of a modern commitment to liberal forms of child development and status attainment (Boli et al. 1985).

Religion, Health, and Nonphysical Senses of Self*

ELLEN L. IDLER, *Rutgers University*

Abstract

The relationship between religion and physical health is a complicated one. In the Durkheimian tradition, and in longitudinal epidemiological studies, religious involvement is shown to have a protective effect on health. Cross-sectionally, however, and even in short followup periods, we sometimes see higher levels of religiousness associated with poorer, not better, health, as people in the midst of crises often turn to religion for comfort and social support. A third way of thinking about the relationship involves self-ratings of health, which appear to represent broad conceptions of self in which physical health and abilities may be deemphasized and nonphysical characteristics, including religious or spiritual self-identities, may be relied upon. Quantitative and qualitative data from a cross-sectional sample of disabled clients of an urban rehabilitation clinic support both of the latter perspectives.

Social scientists in the past several decades, who have been very much interested in health and social life, have generally shown very little interest in the subject of religion and health. For one thing, data sets in which both these complex phenomena are adequately measured are rare; even rarer are followup studies in which causal direction can be accurately assessed. The primary source of funding for health research in the social sciences has been the federal government and, although no explicit restrictions are placed on survey research on religious practices, a de facto restriction has arisen from the principled separation of church and state. The comparative lack of research on religion may also reflect some absence of interest on the part of health researchers. Another reason may be that the relationship between religion and health is so

** An earlier version of this article was presented at the meetings of the Southern Sociological Society, Raleigh, North Carolina, April 1994. The research reported here was supported by the National Institute on Aging FIRST award (AG-07480-02). I would like to thank Shelley Myer and Sharon Cook for their assistance with the data collection and analysis; Linda George and Allan Horwitz and two anonymous reviewers for their comments on an earlier draft of the article; and the physicians, nurse, and most especially the clients of the disability clinic for their candid and thoughtful answers to my questions.* *Address correspondence to Ellen L.  Social Forces, December 1995, 74(2):683-704

complicated. Alternative causal orders are equally plausible, and even the sign of the association is uncertain. *The Oxford English Dictionary* says "complicated" means that which has been "folded, wrapped, or twisted together, combined intimately, and mixed up with in an involved way." This describes the relationship of religion and health very well. Moreover, neither religion nor health is itself a single strand. Religious involvement can mean a mix of practices, beliefs, and identities; health is an even more global concept combining mental, physical, and even social well-being. The purpose of this article is not really to untwist the two, since they appear to occur as naturally interwoven, but simply to look at the knot from several vantage points.

View 1: Religion's Protective Effect on Health

One way to think about religion and health is the way Durkheim ([1897] 1951; [1915] 1965) did. Religion has a beneficial effect on human social life and individual well-being because it regulates behavior and integrates individuals in caring social circles. It provides stability and support, structure and intimacy. Ritual religious practices especially provide these benefits, and religious faiths with high levels of ritual in their worship and private devotional practices tend to benefit more from lower suicide rates (Durkheim [1897] 1951) and better health among the elderly (Idler & Kasl 1992). Even more directly, religious belief systems may include prohibitions against certain behaviors such as smoking, excessive alcohol use, or sexual experimentation, lowering the incidence among religious group members of diseases for which these behaviors are risk factors (Levin & Schiller 1987). Less directly, religious beliefs may provide an overarching cognitive framework for interpreting events, "plausibility structures" that are readily available to individuals to provide coherent meaning for both the small events of the life course and the large events of history (Berger 1967). These mechanisms have sometimes been called the health behavior, social cohesiveness, and sense of coherence hypotheses (Idler 1987; see also Idler 1993a). Because of its multidimensionality, religious involvement could have multiple causal pathways for its effect on physical health.

The causal order in this view is that religious involvement precedes health status; the direction of the association is positive. As in any research on the effect of risk factors on health, the most conclusive research comes from epidemiological studies of large populations with extensive initial health assessments and longitudinal followup of subjects, just the kind of data that do not usually include measures of religious involvement, let alone richly multidimensional ones.

View 2: Religion in Illness and Suffering

Paradoxically, the mirror image of the relationship between religion and health also has a compelling logic. People often turn to religion in times of trouble, including, and especially, during crises of serious illness. Religious groups can offer both spiritual and practical help to the sick: prayers, visitors, and hot meals. Perhaps even more important, they offer to the faithful a comforting

belief in divine authority over human affairs (Pollner 1989). As C.S. Lewis (1962) wrote,

> nor have I anything to offer my readers except my conviction that when pain is to be borne, a little courage helps more than much knowledge, a little human sympathy more than much courage, and the least tincture of the love of God more than all. (10)

Here too, religious involvement is multidimensional. In the language of social research, turning to religion is a kind of emotional coping strategy, one that is especially effective at reducing distress and restoring hope (Kaplan, Munroe-Blum & Blazer 1993) among the elderly (Koenig, George & Siegler 1988) and those experiencing illness or loss (Mattlin, Wethington & Kessler 1990). Religion legitimates the marginal human situations of illness and death by giving them a place in a single sacred reality (Berger 1967). Religious faith, exercised as private prayer, is a cognitive and emotional resource immediately accessible to the sick or disabled (Koenig 1993); the "social" support received from divine others (Pollner 1989) is similarly available, whatever the situation of need. Empirically, then, we should see data in which religious involvement is associated with poorer health cross-sectionally, and even over short followup periods (for examples, see Idler & Kasl 1992; King, Speck & Thomas 1994). In this view, the sign of the association is negative, and the causal order is reversed: health problems precede religious involvement.

In some extreme cases of the religious life, the strength of the negative association can even be intensified. A recent novel, *Mariette in Ecstasy*, is a fictional account of an intensely religious young girl who enters a convent and receives the *stigmata*, the wounds of Christ, in her hands, feet, and sides (Hansen 1991). This is a miraculous occurrence that was first experienced by St. Francis of Assisi, and subsequently by a small number of others whom the Catholic church has recognized and canonized. A negative association between religion and health would result from individuals turning to religion in times of illness, but an even more negative association would be seen when extremely devout individuals actually seek out physical suffering as a means of spiritual purification. Christians believe that not only Christ's death on the cross, but also his suffering there, atoned for their sins. For some, although not many perhaps, physical suffering may take on the religious meaning of identity with Christ; with the mortification of the flesh, the spirit is purified. These are extraordinary individuals, of course, "religious virtuosi," but the issue shows just how complicated things can get.

View 3: Religion and Self-Ratings of Health

A third way of thinking about religion and health hinges on the way health is defined and measured. It involves the self-ratings of health that people give as responses to the survey question, "Would you rate your health as excellent, good, fair, or poor?" Their responses, often considered too subjective to be of use in epidemiological studies, have been shown repeatedly to predict mortality over both short- and long-term periods of followup, even after adjusting for the respondent's medical condition (Mossey & Shapiro 1982; Schoenfeld et al. 1994).

While the meaning of these self-ratings of health remains uncertain, they apparently reflect a respondent's definition of health that encompasses more than just disease status, at least as it has been measured by surveys, medical records, or standard exams by a physician (Idler 1992). In fact, when asked about the meanings attached to their ratings ("When you answered the last question about your health, what did you think of?"), people offer answers citing their ability to work, their feelings of distress, their good or bad health habits, their own health in the past, or the health of others, in addition to their pain and present illness or injury (Groves, Fultz & Martin 1992). Students of the cognitive aspects of survey design have recently become very interested in the multiple meanings respondents assign to their answers to this apparently simple question (Feinberg, Loftus & Tanur 1985; Schechter 1994).

The breadth of the answers suggests that individuals are evaluating many areas of their life when assessing their health — including the health of others in comparison with their own, their emotional well-being, their social relationships, and their ability to perform valued activities in addition to their physical health. The relative weight placed on each of these areas and their patterns will differ from one individual to another. For example, one respondent in the present study, a 28-year-old Asian male with post-polio syndrome, answered that his health was excellent (in spite of the braces on his legs and the cane he walked with):

> My health is excellent. In general, I'm in that part of my life. I'm 28 years old. A lot of people help me get through my life before I go to surgery. I went through the surgery 14 times. Now I can walk. I can do better than before. I'm satisfied with my life that's for sure. Also my family helps me and my friends help me. You have to have other personalities to help you.

Thus in spite of having a debilitating chronic condition, this man emphasizes the support of his social network, his overall satisfaction with life, and his improvement from an earlier period in his life, and it allows him to evaluate what some might consider poor health as excellent.

One can see these evaluations of health as reflecting underlying concepts of the self; for some individuals, peak physical health may be an important aspect of their identity, for others it may be only incidental. The level of physical health necessary for this latter group to perform their social roles effectively or to gain satisfaction from valued activities may be minimal. Stephen Hawking, the physicist with severe multiple sclerosis, or Chuck Close, the painter who was partially paralyzed in midlife, would be extreme examples of people who have made major intellectual or artistic accomplishments despite severe physical debility.

We might very crudely break these areas of the self into two, and call them physical and nonphysical senses of self. Nonphysical senses of self would include cognitive or intellectual abilities, aesthetic interests in music, literature, or art, being a member of a profession, or having satisfying social relationships. The balance of one's physical and nonphysical senses of self might be stable throughout life, or it may shift as we age or experience illness. Charmaz (1991:259) writes that ill people who "define essential qualities of self as distinct from their bodies," especially those who are encouraged by others to do so, are

more likely to transcend the situation of their illness; they have "defined a valued self beyond a failing body." Development or possession of an intact nonphysical sense of self would then be associated with better global self-ratings of health even in the presence of chronic illness.

A religious or spiritual sense of self, the focus of this article, would certainly be among these aspects of identity. We might specifically predict that people who think of themselves as strongly religious or spiritual people would not find that identity threatened by illness or disability; indeed, the socially supportive attention of the religious group, and comfort received from prayer and ritual activities, could strengthen religious beliefs and reinforce such an identity. The sign of the association and the causal order in this third view are identical to the first: religious involvement precedes and is associated with better health. What differentiates the two is the meaning and measurement of the concept of health: self-ratings of health may be relatively positive, even in the presence of serious or chronic illness. There is some evidence for this association: one recent study shows religious practices to be positively related to an index containing two self-ratings of health (Ferraro & Albrecht-Jensen 1991).

Although the three views have been presented as incompatible with each other, their incompatibility is to some extent a heuristic simplification. Ultimately, all causal processes and directions of association could have a place in a complicated picture of processes that occur over time as people age, health events occur, and religious involvement declines or grows.

The hypotheses for this study are derived from the latter two ways of thinking about religion and health. First, with respect to the religious response to illness and suffering, we expect to see that respondents with poorer health or greater disability are more likely to say they have sought help from their religion. Second, with respect to religious and nonphysical senses of self, we expect to see that respondents with stronger religious senses of self-identity and better self-ratings of health will have a stronger nonphysical sense of self.

Method

SAMPLE

The participants in this study were randomly selected from clients of an urban rehabilitation clinic. The present study was part of a larger effort to better understand the meaning of self-ratings of health, with the eventual goal of discovering the processes by which these highly predictive self-ratings are generated. The strategy for the study was to focus on clients whose self-ratings were different from what might be expected from their observed physical health.

To identify such individuals, two instruments from the NHANES-I (National Center for Health Statistics 1977) were used to compare data on the same condition from two independent sources: a physician's examination of the client's musculoskeletal system and the patient's own self-report of pain in those same joints. The protocol for the physician's exam was the musculoskeletal exam portion of the first National Health and Nutrition Examination Survey (NHANES-I) (National Center for Health Statistics 1977). The examination

requires the physician to manipulate, flex, extend, bend, and rotate the client's joints, noting tenderness, swelling, deformity, limitation of motion, pain, and other symptoms of the knees, hips, back, neck, shoulders, elbows, wrists, ankles, feet, fingers, and toes. The second instrument, measuring the respondent's perceptions, was the *Arthritis Supplement* to the NHANES-I (National Center for Health Statistics 1977), a detailed set of questions about the individual's experience of pain, stiffness, and swelling in the knees, hips, back/neck, and other joints, which corresponds closely to the physician's examination.

Two hundred clients were screened with both instruments, representing a completion rate of 63.3%, to locate individuals who were reporting more pain than might be expected on the basis of their physical exam, and also those who reported less. These "pain" and "exam" scores could then be compared to the nationally representative NHANES-I sample from which the measures were taken.

Scores for the physician's evaluation (Exam) and the corresponding client reports of joint pain (Pain) were converted to Z-scores and the difference was taken, so that higher (positive) scores represented relatively greater physician findings, and lower (negative) scores represented greater reported pain. A similar difference variable was calculated for the entire original NHANES-I sample. Respondents in the clinic sample whose scores were one or more standard deviations away from the mean of the same variable for the NHANES-I sample were asked to participate in the psychosocial interview. Ironically, the screening was mostly unnecessary. In the NHANES-I sample, approximately 15% of the sample fell outside the one standard deviation line; in the clinic sample it was 88%. In other words, the great majority of the clients screened had pain reports that were different from what would be expected on the basis of their physician's exam. Because the clinic respondents' scores were compared to the NHANES-I distribution, not their own, this finding is *not* an artifact of the distribution of clinic scores. Most important, these scores were about evenly split between overreporters and underreporters.

Of the 176 clients who were screened into the second part of the study, 7 refused to participate further, 3 died or were hospitalized, and 20 could not be recontacted with the information they had given. This yielded 146 psychosocial interviews, or an 83% completion rate for the second part of the study.

MEASURES

Findings from the NHANES-I physician exam were summed for all sites.

For the *Arthritis Supplement*, if clients responded *no* to each of five screening questions, they were considered to have no musculoskeletal pain. As the emphasis in the present study was also on the interpretation of current states, respondents who reported pain of any duration that had not recurred in the last year were also considered to have no pain.

The health assessment instrument also includes the 38-item chronic conditions history of the NHANES-I Medical History Questionnaire (National Center for Health Statistics 1977), a body systems symptom review instrument — from which musculoskeletal symptoms were omitted for the purposes of this study (Cameron, Leventhal & Leventhal 1993); a 10-item physical abilities

battery used in the Rand Health Insurance Experiment (Brook et al. 1979) that asks the respondents about their ability to do simple activities (such as dressing and walking inside the house) and more difficult tasks (such as housecleaning and participating in sports), sociodemographic variables, health practices, and the single-item self-rating of health ("in general, would you say your health is excellent, very good, good, fair, or poor?"). This questionnaire was administered to the clients as soon as possible after the physician's examination, usually immediately.

The chronic-condition items were developed into two measures, one summarizing the respondent's chronic disease burden that puts them at risk for mortality and the other for chronic diseases that do not have a mortality risk but do cause disability. The measures were based on analyses of 16-year age-adjusted mortality risks by condition in data from the 1987 NHANES-I Epidemiologic Followup Study (NHEFS) (National Center for Health Statistics 1992).

The psychosocial interview took about one hour to complete. It combined frequently used scales and open-ended questions on a variety of subjects, including religion. Because self-ratings of health appear to reflect broad areas of emotional and social well-being and outlook on life (Adelman 1994; Maddox 1964), topics covered in the interview included social networks and support (Norbeck, Lindsey & Carrieri 1981), depression (Radloff 1977), neuroticism (Eysenck 1958), optimism (Scheier & Carver 1985), body consciousness (Miller, Murphy & Buss 1981), religious affiliation, activities, beliefs, and self-rated religiousness (Hoge 1972; McCready & Greeley 1976), and a set of items measuring the nonphysical sense of self. The last scale was developed specifically for this research, to elicit the importance the respondent placed on various aspects of nonphysical (social, intellectual, aesthetic, spiritual) identity. Thus they were asked, on a scale of 0 to 10, "to what extent do you think of yourself as a *musical* person? (Probe: If 10 is the most *musical* you could be, and 0 is not *musical* at all . . .?)" The 15-item scale appears in the Appendix to this article.

We used three measures of religious involvement. The first is a self-assessment of religiousness, based on the two asterisked items in the Appendix. The second is a measure of religious activities, including attendance at services and other religious activities, reading the Bible, knowing other people in the congregation, and watching religious programs on television. Finally, because of this article's concern with the issue of seeking help from religion for health problems, responses to an open-ended question were coded dichotomously for whether the respondent had received help or not. The respondent's religious affiliation was also recorded.

ANALYSIS

Cronbach's alphas were calculated for the appropriate scales: self-rated religiousness alpha = .63, religious activities alpha = .76, neuroticism alpha = .72, optimism alpha = .77, social body consciousness alpha = .67, depression alpha = .91, and nonphysical sense of self = .77.

Scale analysis, bivariate, logistic regression, and ordinary least-squares regression analyses were conducted for the two dependent variables: help from

religion and nonphysical sense of self. Multivariate analyses were given a hierarchical structure, with the religion variables entering the model first, to distinguish the dependent variable from other dimensions of religiosity. Sets of variables were then introduced one at a time; in the second step the key independent variables for health were added, and possible confounding demographic variables at the third step. Possible explanatory factors of health practices were added at the fourth step, social networks and support at a fifth step, and psychological characteristics and distress were added at the sixth step. Variables were included in the sets only if they had a significant bivariate association with the dependent variable in initial analyses; nonsignificant variables ($p<.10$) were dropped to reduce the number of variables in the model at any one time.

Results

Because this study adopted some of its instruments from those used with a nationally representative sample, the disability clinic sample can be compared with the larger sample (Idler 1993b). Respondents in the clinic sample were about evenly split between males and females, but the clinic respondents were much more likely to be nonwhite and unmarried, and they were somewhat more educated than the NHANES-I sample. The clinic sample had poorer self-rated health, more mortality-risk and disability-risk chronic conditions, poorer musculoskeletal status by physician's evaluations, and greater reports of pain.

Variables to be included in the analysis are described in Table 1. The two dependent variables, help from religion and nonphysical sense of self, are not at all correlated with each other.

Self-rated religiousness is highly correlated with receiving help from religion, as are race, education, and income. The other measures of religious involvement (activities and beliefs) do not appear because, while they were also highly correlated with receiving help from religion, they were too highly correlated with self-rated religiousness to be included together in a multivariate analysis. Nonphysical sense of self is not highly correlated with anything, although it has small associations with social support and neuroticism.

Table 2 shows the religious heterogeneity of the sample. Protestant respondents were more often nonwhite and younger than Jewish and other respondents. Roman Catholics were about evenly split between white and nonwhite and had the least education of the groups. Jewish respondents were more likely to be female, were all white, and had the oldest average age. Those with "other" or no religious affiliation were the most educated. Because of the demographic differences between the groups, and because of the similarities between Jewish and other/none respondents, two dummy variables, for Protestants and Catholics, were coded and included in all analyses. Jewish and other/none respondents were far less likely to report receiving help from religion. Nonphysical senses of self do not differ significantly among the groups.

The multivariate analysis begins in Table 3. The hypothesis whose testing is displayed in this table is that respondents with poorer health will be more likely to have sought help from religion. Variables included in the table are entered in

TABLE 1: Descriptive Statistics for Variables Used in Analysis, Disability Clinic Study

Variable	N	Minimum	Maximum	χ	Pearson r Help	Pearson r Nonp.
Help from religion	138	0 = Not mentioned	1 = Mentioned	0.6	1.00	.01
Nonphysical sense of self	143	23 = Low	111 = High	75.8	.01	1.00

TABLE 2: Descriptive Statistics for Religious Affiliation Categories

Religious Preference	Percent	Percent Female[a]	Percent White[b]	Mean Age[c]	Mean Educ.[d]	Percent w/ Help from Religion[e]	Mean Nonphys. Sense of Self[a]
Protestant	31.5	55.6	20.0	43.2	12.7	31.2	76.9
Catholic	30.8	61.4	47.7	43.4	12.1	31.9	74.5
Jewish	17.5	80.0	100.0	65.1	14.4	16.7	73.6
Other/ none	20.3	62.1	51.7	53.0	15.1	20.3	78.1

[a] No significant differences between groups
[b] $\chi^2 = 41.3$, 3 df, $p < .0001$
[c] $F = 11.46$, 3 df, $p < .0001$
Bonferroni adjustment shows Jewish respondents older than all others.
[d] $F = 6.68$, 3 df, $p < .0003$. Bonferroni adjustment shows Roman Catholics with less education than all others, Other with more.
[e] $F = 7.3$, 3 df, $p < .0001$. Bonferroni adjustment shows Jewish respondents less likely than all others to receive help from religion.

sets from those that were significantly associated with receiving help from religion in Table 1. Tables 3 and 4 show standardized coefficients.

The analysis begins with model 1, considering just the religion variables. Respondents who think of themselves as strongly religious people are much more likely to say they have received help from religion, as are Protestants when compared with the Jewish/other/none respondents.

In model 2 we add the health measures that had a significant association with receiving help in Table 1, functional disability, cognitive status, and chronic disease disability risk. Only the disability measure is associated with receiving help, and this measure is retained throughout. In model 3 are added the sociodemographic factors; nonwhite respondents were much more likely to say they had received help, and lower levels of income and education were marginally significant, so all three are retained. Note that the significant effect of being Protestant disappears because of the strong effect of race.

In model 4 the health risks of alcohol use and inactivity are added; inactivity has a negative association with receiving help. In model 5 the psychological characteristics of neuroticism, optimism, body consciousness, and depression are added, but there are no significant relationships among them.

Thus, for view 2, the hypothesis is confirmed: the more disabled people are, the more likely they were to say they had sought help from religion. The direction of the association is that poorer health is associated with greater religiousness. This association is net of the respondents' ratings of their own religiousness, race, education, and activity levels.

* p < .05   ** p < .01   *** p < .001

In Table 4 we see the analysis of nonphysical sense of self. The direction of the hypothesized relationship with self-rated religiousness is the same as it was for help from religion; people with a stronger religious or spiritual sense of self should have a stronger overall nonphysical sense of self. The hypothesized direction for self-rated health, however, is different from the disability/help from religion association in the same way that view 2 is opposite to view 3: we expect people with a stronger nonphysical sense of self to have better self-rated health.

The analysis follows a similar strategy. In model 1, including just the religion variable self-rated religiousness is associated with nonphysical sense of self, but Protestants and Catholics show no differences from the Jewish/other/none respondents. These associations are not changed when self-rated health is added.

In the next column, the sociodemographic factor of education is added. It is marginally significant and is retained in further steps; as one would expect, higher levels of education correspond with greater nonphysical senses of self. Among the health practices, which originally included smoking, alcohol and illicit drug consumption, and inactivity (lack of exercise), only lack of exercise was associated at the bivariate level with either help from religion or nonphysical sense of self. Lack of exercise is entered in the fourth column here, and it shows no significant association with nonphysical sense of self.

Several aspects of social networks and support were associated at the bivariate level with nonphysical sense of self, but none of the associations are significant when tested in the multivariate model.

Last, we look at some psychological characteristics, which had significant bivariate associations. None of them, however, is significant in the multivariate analysis.

Thus the most parsimonious model containing all significant effects is model 3, in which the nonphysical sense of self is associated with higher levels of religiousness, better self-ratings of health, and to some extent, higher levels of education, as was hypothesized.

Discussion

This study has many limitations; at best it can be considered illustrative and preliminary. The sample is small and highly selected for individuals with health problems. Moreover, it is a cross-sectional study in a field in which the causal directions are especially problematic. At most it can suggest directions for future studies of religion and health.

With these limitations in mind, however, the seemingly paradoxical hypotheses for this study were both supported, and they show that religion does have a complicated relationship with health. The first hypothesis was that respondents with greater disability would be more likely to say they had sought help for their health problems from their religion. This yes/no response was coded from what was actually an open-ended question in the interview: "Do your religious beliefs help you at all with your health problems? Can you tell me in what way, or give me any specific examples of help that you received?"

There were many interesting answers to this question; 62% of the sample gave a positive response. In fact, the respondents' stories illuminate both findings of the study; they especially provide insight into the meaning of identities based on spiritual or religious criteria.

SPIRITUAL AWAKENINGS

First there are accounts from respondents who felt that help from God or their religion changed everything in their lives. Perhaps the most dramatic stories were of religious awakenings that took place directly as a result of a sudden illness or injury.

> I don't know . . . I felt so spiritual, you know [after the stroke]. It was such a — you know — a beautiful experience. I get like that every now and then. . . . I got this relaxed feeling and feel so good. I don't think you could feel that good all the time. We couldn't walk around feeling like that daily. One thing, I stopped worrying as much as I used to, and I been able to let go of certain things that I couldn't let go of before. And, you know, I used to sit and cry because I was so happy. Yeah, it's a great way to feel. . . . I learned to be by myself. I get lonely sometimes . . . but I can deal with it more now. So in a sense I look at my stroke as a blessing. . . . I think . . . through this stroke I started to feel more spiritual.

These are the words of a 51-year-old black Protestant woman who had been a typist before her stroke. She is still partially paralyzed and speaks elsewhere of looking down at her hands, which she cannot move. Rather than regret, however, at her loss of her skill and ability to earn a living, she thinks of those who have had a stroke and died, and she feels lucky to be alive. More than that even, she feels that her life has been enriched by the experience, so much that she used to "sit and cry because I was so happy" and actually speaks of her stroke as a blessing. There were other such stories. Another was from a 35-year-old black Protestant woman who had also been a secretary and had also had a stroke:

> At the time before my stroke I had no experience with my God. With my stroke I learned from him. It happened with faith. My pastor and my friends talked to me about religion. I was not very serious about religion. I take God seriously, deeply. People in my church pray for me and visit me all the time. They call me and give me support.

Both these women identified their illnesses as real turning points in their religious lives, although they imply that they had had some connection with religion ("my pastor and my friends talked to me") before the event. One man, also a Protestant, 52 years old, white, a fabric designer who was paralyzed after a mugging in which he was stabbed in the back, explained,

> When your life drastically changes I think if you had any religious training or background you tend to resort or turn to it or think of it or find it more enhancing or helpful. Due to my injury I've become more religious.

Whether they are awakenings or reawakenings isn't really important. What is important is that these respondents saw a growth in their spiritual lives that coincided with, and came about as a direct result of, their shrinking physical capacity. A loss in one area of life became a gain in another. It is especially clear

when the respondents had some degree of paralysis, an unambiguous loss of physical ability. It is a causal chain these people are telling us about, one in which they consciously make the direct connection between the helping functions of religion and the nonphysical, religious or spiritual sense of self. One more example is from a 25-year-old Protestant Hispanic male who had injuries that resulted in memory loss and speech problems:

> Through my injuries I'm so depressed. When I go to church, I feel so much better. It relieves me. A few times I've been to church, I "caught the Spirit." And after that I felt so much better.

DISCOVERING PURPOSE IN LIFE

There were some other respondents who spoke about religious awakening in a different way, not as a feeling of spirituality, but as a conviction that God had a purpose for them. A number of these people's illnesses or injuries had brought them close to death, and the very fact of their survival took on a religious meaning, causing them to see their lives in a new way. One man was a 42-year-old Russian immigrant, a bus driver, who had fallen five flights of stairs and injured his pelvis and head and had nerve damage (his religious affiliation was "other," for Russian Orthodox):

> When I had my accident, I had spent time in a coma for three weeks. And finally I survived, and was on my way to recover, and I think that if God saved my life, he had a purpose. So I believe him, and I'm not going marching down.

Another man, a 40-year-old Hispanic, Roman Catholic man whose legs had both been amputated after a train accident said simply,

> I thank God. There is a purpose to why I'm still alive.

HEALING, STRENGTH, AND COMFORT

In many other cases, there was, in addition to gratitude for being alive, also gratitude for the recovery they had experienced, which they often framed in terms of religious healing. Perhaps the single most dramatic example came from a pretty young Protestant Hispanic woman who had suffered severe head injuries in a car accident. She limped slowly into the interview room on crutches and with braces on both legs. She told me she had been in a coma for three months:

> [The doctors] told me I would never walk again. [What helps me is] trusting in God, knowing when it's his time. I ask for his help and he always helps me. He is there caring for me, he's dependable.

The interviewer said, "And you just walked in here." And she beamed. Another woman (Roman Catholic) who asked God directly for healing and felt she received it was 63 years old and had immigrated from the Virgin Islands. She had had a stroke, was using a walker, and still had partial paralysis in one arm:

> When I was in the hospital, when I woke up and I couldn't feel nothing, I figured that I would be an invalid. I would be in a wheelchair, and people would have to do things for me. And then I started praying, asking Jesus to help me, give me strength, that I could do

the things, and have nobody wait on me. My prayer was answered. I've come a long way, and I have to give thanks to almighty God. I have to thank my God every day.

Another example is from a young black Protestant woman who fell four stories from her apartment in a fire:

I think that believing in God . . . a lot of people thought I was going to die. I'm making it. Even the doctor told me that I have nine lives because they almost gave me up. With God's help I'm walking around. I didn't move around for eight months. I was on my back. I couldn't do anything for myself. Now with the help of God I'm doing all these things.

There were several other respondents who reflected directly on the relationship between the healing that comes from medicine and the healing that comes from faith. For example,

When medicine can't help, God does. He's the doctor of all doctors.

A 45-year-old black auto repairman, a Protestant, who had had a stroke said

[My religious beliefs] helped 100%. When I was going to the church I couldn't walk. I prayed a lot and I noticed I made an improvement. I believe it was partly because of the prayer. Again, it's the Lord who made us. He's the one who knows about us. Doctors are directed by the Lord. The physician's knowledge comes from God. I'm sick with a stroke and the doctor might say I'm not going to walk or I may not be able to live again. They are directed by the Lord. I think all my improvement comes from God.

Respondents conceived of "help" in many different ways. Short of attributing any healing to their faith, many respondents at least felt they gained peace, encouragement, strength, and comfort. Here is a sampling of responses:

I try to think of the hereafter. That gives a little optimism I think. Just the occasional dropping into church gives some encouragement. (69-year-old white Roman Catholic woman, former secretary with back pain)

The doctor said if the car hit me by another inch I would have been crippled. God helped me with that. In my depression I've asked him to give me the strength and to lift my burdens. (43-year-old black Protestant man, computer supervisor)

It's helped me overcome. I didn't take public transportation, but now I take it. God makes me feel brave. I feel more independent. (32-year-old Asian woman, Protestant, data entry worker with post-polio syndrome)

If I'm in pain whether it be physical or mental, I pray for strength and guidance and I feel that I've gotten it. (36-year-old black woman, Protestant, clerical worker with epilepsy)

Yes, it's comforting knowing that God is there to help me deal with pain and everything else in life. (40-year-old black man, Roman Catholic, office associate with vascular problem)

FINDING A MEANING IN SUFFERING

There was also a theme of enduring suffering that several respondents developed. Some framed their experiences in terms of being tested by God, and believing that their faith would be rewarded in the future. These were respondents who could point neither to tangible physical healing nor to intangible emotional comfort, but who believed that their present suffering must have some religious meaning. Here are some examples:

I am attending a group that believes in reincarnation. We discuss what the soul is, what a person is. I believe life is a learning experience. I believe the soul goes through many lifetimes. I believe that my disability is something that I have to go through to sort of get back on the right path of evolution. We are all evolving into something perfect. People who choose difficult lives choose them to learn from them. (43-year-old Jewish female, newsstand worker with arthritis of the knee)

Job suffered and endured due to his faith in God. His reward then was twice as much. Endurance is the most important thing and faith that he does exist and that if we do his will the rest comes. (49-year-old Hispanic Protestant woman, saleslady suffering pain and depression)

My friend, when she was sick, she never thought that she was going to die. She thought that maybe God was thinking about her and wanted to see if she really had faith in him. (22-year-old Hispanic woman with lupus. She spoke so often during the interview of "her friend" that one wonders if she wasn't really talking about herself)

Because they say God has no respect for individual persons. Anyone can get sick because tomorrow isn't promised to anyone. Just thank God for one more day. Anything can happen. It's scary, you have people, family, kids. The environment around us, you tend to worry about families. I feel prayer helps. Reading in the Bible that Job had to go through sickness even though he was a perfect and upright man and everything. God blessed him more and gave him a new family. (24-year-old black Protestant woman with multiple sclerosis)

These accounts are among the most thoughtful and subtle that were given heard. They show a poignant level of reflection, a sense of prayers prayed but not answered, a struggle, a real groping for meaning that does not come easily. Their identification with the biblical figure of Job, especially, shows the unresolved nature of their suffering.

Like Job, some respondents were also angry with God for allowing evil in the world, or cruelty, or neglect. One 76-year-old actress who had no religious affiliation and had suffered a stroke was being interviewed during the Los Angeles riots. She said

You could make a case for that [that religious beliefs help people with their pain or health problems]. I could make a case. I sometimes read things and I become completely swayed by what I read and then I think, well, I get cynical about it. I can't answer that question. I wish I had that connection, I really do. I've prayed in my life. I prayed a lot when I was little. When something happens like it's happening now in Los Angeles, how can you think that this God in heaven cares about you? It's stupid.

Another woman, a 53-year-old Hispanic Roman Catholic who had had an aneurysm, gave a classic account of the problem of the existence of evil in the world:

I should be more closer to God, you know. I can't believe that I'm like this. God is supposed to be kind, love, you know. People say that, I can't. If God is supposed to be so kind, so helpful, he would cure me if I was sick. Quote the Bible, blind people, crippled people heal ye . . . . from death. How come he wants people to go hungry? To be paralyzed, even kill each other? God cannot be giving me this cause I refuse, coming from the Devil, the Devil is mean. But that's different stuff. Or maybe I wicked in my own self and I don't know it, and I deserve this. We've been punished ever since Adam and Eve. So maybe I would say well then why should I worry about it. They did it and that's how we have to pay for it. Maybe I should take this penalty, but I can't. Because I should not pay for what they did.

Another woman blamed God more indirectly, for the failings of the people around her to help her as she thought they should. This was a 36-year-old Hispanic woman, a Roman Catholic:

God helps me in a lot of ways. But he put people in this world to help and I don't see anyone helping me in the things I really need. I need physical therapy, understanding, and to treat me like a normal person. I'm just like everybody else. I'm not getting the help I need.

THE SPIRITUAL, NONPHYSICAL SELF

The argument in this article has been that one of the benefits of religious involvement will be in refocusing the respondent on aspects of the self to which a painful, or nonfunctioning, or unattractive physical body is irrelevant. The inner, spiritual self can be beautiful and whole even when the material, physical body is broken or diseased. As these are important teachings of the Christian religion, it is not surprising that the responses above come almost exclusively from Protestants and Roman Catholics. But there was another important group of responses from people who were Jewish or identified their religious affiliation as other or none, and who also regarded their spiritual self as very important. One woman, a 37-year-old writer with Guillan-Barré syndrome said,

Yes [her religious beliefs helped her] because of the meditation. You lay down and localize where your pain is. From there you take the pain and you have a spirit at the end of the bed that receives the pain. You watch the pain go off. You go over every step of relaxation until the pain goes away. I've only been going there for two months. . . . there is a Science of Mind Center that I go to on the weekends. They have a healing circle and prosperity groups that focus on living a happy and healthy life-style without medication. There are practitioners there and a reverend. There is a religious aspect to it.

Another woman, a 48-year-old Jewish musician who had Ehlers-Danlos syndrome, a hereditary disease of the connective tissue, said

My inner values, my nonmaterial world values, are very helpful with my pain. I don't call it religion. I work with my body energy and my emotional energy. I use my visualizing techniques to manipulate my mind. To me they are spiritual exercises, choosing life as opposed to being struck down by my situation.

Finally, here are some passages from the very lengthy response of a 65-year-old European immigrant; she had had breast cancer some years before and was currently seeking treatment for arthritis. She was a professor and identified her religious affiliation as "other":

As I come close to my exit, I come to what Erikson calls "the closing of the circle." I was inspired by Herbert Benson and Norman Cousins. It is the state of being you are in, I am at peace with myself — our bodies can fight cancer themselves. I pat my breast, I say "Tootsie, we have to coexist. If I am cremated you are too." If it is not to be, God whoever you are, okay then please let me stay a little longer, and then go as fast as possible. I don't think suffering is noble. . . . I'm trying to explain what is beyond language. I'm smarter than this, it is liberating, I can go into any of them [churches] and feel at home. I don't live in fear — I am in resolution in my unconscious.
